1.1 Science and the Natural World

Name	Class	Date
Write true if the st	atement is true or false if t	the statement is false.
1. A hypoth	esis must be based on scie	entific knowledge.
2. A scienti	fic theory is a guess about	how or why something happens.
3. Scientist	s make predictions that tell	l what will happen under any and all conditions.
4. The scien	ntific method includes the	steps involved in a scientific investigation.
5. "Did life	on Earth evolve over time	e?" This question can be answered scientifically.
6. Experim	ents are performed under c	controlled conditions.
7. Scientist	s can study all aspects of the	he natural world, including experimenting on an extinct animal.
8. The depe	ndent variable is always th	he opposite of the independent variable.
9. Commur	icating your results allows	s others to test your hypothesis.
10. Experin	nental evidence that agrees	s with your prediction supports your hypothesis.
11. The firs	t step in a scientific investi	igation is always to develop a hypothesis.
12. Scientis	ts gradually build an incre	easingly accurate and detailed understanding of the natural world
13. Newton	discovered the law of grav	wity when an apple fell from a tree and hit him on the head.
14. Scientif	ic evidence is any type of	data that may either agree or disagree with a prediction.
15. Scientif	ic theories are broad expla	anations that are widely accepted as true.
Lesson 1.1: (Critical Reading	
Name	Class	Date

Nature Can Be Understood

Read these passages from the text and answer the questions that follow.

Scientists think of nature as a single system controlled by natural laws. By discovering natural laws, scientists strive to increase their understanding of the natural world. Laws of nature are expressed as scientific laws. A scientific law is a statement that describes what always happens under certain conditions in nature.

An example of a scientific law is the law of gravity, which was discovered by Sir Isaac Newton. The law of gravity states that objects always fall towards Earth because of the pull of gravity. Based on this law, Newton could explain many natural events. He could explain not only why objects such as apples always fall to the ground, but he could also explain why the moon orbits Earth. Isaac Newton discovered laws of motion as well as the law of gravity. His laws of motion allowed him to explain why objects move as they do.

Science Cannot Answer All Questions

Science rests on evidence and logic, so it deals only with things that can be observed. An observation is anything that is detected either through human senses or with instruments and measuring devices that extend human senses. Things that cannot be observed or measured by current means — such as supernatural beings or events — are outside the bounds of science. Consider these two questions about life on Earth:

- Did life on Earth evolve over time?
- Was life on Earth created through another method?

The first question can be answered by science on the basis of scientific evidence and logic. The second question could be a matter of belief. Therefore, it is outside the realm of science.
Questions
1. What is an observation?
2. What is a scientific law?
3. What scientific law explains why the moon orbits the Earth? What does the law state? Who developed this law?
4. Complete this sentence: Natural laws allow scientists to

5. Can science answer all questions? Justify your answer.

Lesson 1.1: Multiple Choice

Name	Class	Date

Circle the letter of the correct choice.

- a. Assumptions scientists make include:
 - a. Nature can be understood through systematic study.
 - b. Scientific ideas never need to be revised.
 - c. Science can provide answers to all questions.
 - d. all of the above

b. A hypothesis

- a. is the first step in a scientific investigation.
- b. is based on what a scientist believes.
- c. is a possible question to a scientific answer.
- d. can be proved incorrect.

c. A scientific theory

- a. is based on lots of evidence.
- b. is a guess about how or why something happens.
- c. can never be altered or changed.
- d. none of the above
- d. Which is the correct order in a scientific investigation?
 - a. ask a question, test the hypothesis, communicate results, draw conclusions
 - b. make observations, ask a question, form a hypothesis, test the hypothesis
 - c. draw conclusions, ask a question, form a hypothesis, test the hypothesis
 - d. ask a question, make observations, test the hypothesis, draw conclusions
- e. To test a hypothesis,
 - a. a scientist first collects evidence.
 - b. a scientist first draws conclusions.
 - c. a scientist first makes a prediction.
 - d. a scientist first makes observations.

f. An experiment

- a. is performed under controlled conditions.
- b. generally tests how one variable is affected by another.
- c. contributes important evidence that helps scientists better understand the natural world.
- d. all of the above

i. science

- g. Food chains are scientific models that
 - a. represent simple systems in nature.
 - b. make the scientific systems easier to understand.
 - c. are based on mathematical equations.
 - d. are based on a prediction.
- h. Science cannot answer all questions.
 - a. The above statement is true because science cannot answer matters of belief.
 - b. The above statement is true because all science is based on logic.
 - c. The above statement is false because science can prove that life evolves over time.
 - d. The above statement is false because science is based on observations and evidence.

Lesson 1.1: Vocabulary I
Name Class Date
Match the vocabulary word with the proper definition.
Definitions
1. a statement that describes what always happens under certain conditions in nature
2. a possible answer to a scientific question
3. any type of data that may either agree or disagree with a prediction
4. a plan for asking questions and testing possible answers
5. a representation of part of the real world
6. a broad explanation for events that is widely accepted as true
7. detected either through human senses or with instruments and measuring devices that extend human senses
8. a special type of scientific investigation that is performed under controlled conditions
9. developed the laws of motion
10. a statement that tells what will happen under certain conditions
11. developed theory of relativity
12. a distinctive way of gaining knowledge about the natural world
Terms
a. Albert Einstein
b. evidence
c. experiment
d. hypothesis
e. Isaac Newton
f. model
g. observation

Lesson 1.1: Criti	ical Writing	
Name	Class	Date

Thoroughly answer the question below. Use appropriate academic vocabulary and clear and complete sentences.

Discuss why science is not able to answer all questions. Incorporate the steps of the scientific method into your

6

response.

1.2 Biology: The Study of Life

Less	son 1.2: True or False
Name	Class Date
Write	true if the statement is true or false if the statement is false.
	1. A cell is the basic unit of the structure and function of all living things
	2. An adaptation is a characteristic that helps a living thing survive and reproduce.
	3. Natural selection is a change in the characteristics of living things over time.
	4. A population consists of many different species.
	5. Charles Darwin developed the theory of evolution by natural selection.
	6. All living things must maintain homeostasis.
	7. The characteristics of all living things are controlled by genes.
	8. The four unifying principles of biology are the cell theory, the gene theory, homeostasis, and gravity.
	9. Deer sometimes eat the starlings (birds) that sit on them.
	10. The cells of many different organisms are very similar.
	11. Simple life forms, like bacteria, have simple chemistry.
	12. Simple life forms, like bacteria, do not grow and develop.
	13. Every living thing begins life as a single cell.
	14. The mole's touch organ is an adaptation because it helps the mole survive in its dark.
	15. There are at least 100 million different species live on Earth today.
Less	son 1.2: Critical Reading
Name	Class Date
Read i	this passage from the text and answer the questions that follow.

Evolution of Life

The diversity of life on Earth today is the result of evolution. Life began on Earth at least 4 billion years ago, and it has been evolving ever since. At first, all living things on Earth were simple, single-celled organisms. Much later, the first multicellular organisms evolved, and after that, Earth's biodiversity greatly increased.

Today, scientists accept the evolution of life on Earth as a fact. There is too much evidence supporting evolution to doubt it. However, that wasn't always the case.

Darwin and the Theory of Evolution

The idea of evolution has been around for centuries. In fact, it goes all the way back to the ancient Greek philosopher

Aristotle. However, evolution is most often associated with Charles Darwin. Darwin published a book on evolution in 1869 titled *On the Origin of Species*. In the book, Darwin stated the theory of evolution by natural selection. He also presented a great deal of evidence that evolution occurs. Despite all the evidence Darwin presented, his theory was not well received at first. Many people found it hard to accept the idea that humans had evolved from an ape-like ancestor, and they saw evolution as a challenge to their religious beliefs. Darwin had actually expected this type of reaction to his theory and had waited a long time before publishing his book for this reason. It was only when another scientist, named Alfred Wallace, developed essentially the same theory of evolution that Darwin put his book into print.

Although Darwin presented a great deal of evidence for evolution in his book, he was unable to explain how evolution occurs. That's because he knew nothing about genes. As a result, he didn't know how characteristics are passed from parents to offspring, let alone how they could change over time.

Evolutionary Theory After Darwin

Since Darwin's time, scientists have gathered even more evidence to support the theory of evolution. Some of the evidence comes from fossils, and some comes from studies that show how similar living things are to one another. By the 1930s, scientists had also learned about genes. As a result, they could finally explain how characteristics of organisms could pass from one generation to the next and change over time.

Using modern technology, scientists can now directly compare the genes of living species. The more genes different species share in common, the more closely related the species are presumed to be. Consider humans and chimpanzees. They share about 98% of their genes. This means that they shared a common ancestor in the not-too-distant past. This is just one of many pieces of evidence that show we are part of the evolution of life on Earth.

Ouestions

1.	What	were	the	first	living	things	on Earth?

2. Who is most often associated with developing the theory of evolution?

3. What is the name of the process by which evolution occurs?

www.ck12.o	rg
------------	----

4. What discovery allowed scientists to explain how characteristics are passed from parents	to offspring?	?
---	---------------	---

5. Cite one piece of evidence that demonstrates we are evolutionarily closely related to chimpanzees.

Lesson 1.2: Multiple Choice

Name	Class	Doto
Name	Ciass	Date

Circle the letter of the correct choice.

- a. The cell theory states that
 - a. all living things are made up of cells.
 - b. living cells may come from other living cells.
 - c. all living things remain single-celled.
 - d. all of the above
- b. Levels of organization of an individual organism includes
 - a. the tissue.
 - b. the population.
 - c. the community.
 - d. all of the above

- c. Which is the best definition of "biology"?
 - a. The science of living organisms.
 - b. The study of humans and animals.
 - c. The study of plants, humans, and animals.
 - d. The science of life.

d. Homeostasis is

- a. the ability to give rise to offspring.
- b. maintaining a stable internal environment.
- c. the ability to detect and respond to changes in their environment.
- d. the ability to grow and develop.

e. Evolution

- a. is a change in characteristics of living things over time.
- b. occurs by natural selection.
- c. explains how modern organisms have descended from ancient life forms.
- d. all of the above
- f. An example of a symbiotic relationship in which one organism is harmed is
 - a. the relationship between a flock of starlings and a red deer stag.
 - b. the relationship between a lion and an antelope.
 - c. the relationship between hummingbirds and flowers.
 - d. the relationship between humans and their pet dogs.

g. Cells

- a. are all unique; no two cells are similar.
- b. come from other cells, except for the very first cell of a new organism.

Data

- c. are the basic unit of structure and function of all living things.
- d. are all circular in shape.
- h. To be classified as a living organism, an object must
 - a. maintain homeostasis.
 - b. have a complex chemistry.
 - c. be made of at least one cell.
 - d. all of the above

Less	on 2.1: True or False
Name	Class Date
Write	rue if the statement is true or false if the statement is false.
	1. An atom is smaller than an element.
	2. Organic compounds are found in living organisms.
	3. Proteins are made out of amino acids.
	4. Proteins speed up chemical reactions.
	5. The DNA code carries instructions for the correct sequence of nucleic acids in a protein
	6. Sugars and phosphate groups form the middle of a nucleic acid chain.
	7. DNA (and RNA) is made out of nucleotides.
	8. A protein consists of one or more polypeptide chains.
	9. Lipids include fats, oils, and sugars.
	10. Carbohydrates are the most common type of organic compound.
	11. Peanut oil is an unsaturated fatty acid.
	12. Cytosine and adenine are complementary bases in DNA.
	13. A double helix is like a spiral staircase.
	14. Phospholipids form cell membranes.
	15. Carbohydrates are made out of monosaccharides.
Less	on 2.1: Critical Reading
Name	Class Date
Read t	hese passages from the text and answer the questions that follow.

The Significance of Carbon

A compound found mainly in living things is known as an **organic compound**. Organic compounds make up the cells and other structures of organisms and carry out life processes. Carbon is the main element in organic compounds, so carbon is essential to life on Earth. Without carbon, life as we know it could not exist. Why is carbon so basic to life? The reason is carbon's ability to form stable bonds with many elements, including itself. This property allows carbon to form a huge variety of very large and complex molecules. In fact, there are nearly 10 million carbon-based compounds in living things! However, the millions of organic compounds can be grouped into just four major types: carbohydrates, lipids, proteins, and nucleic acids. You can compare the four types in **Table** 2.1. Each type is also described below.

TABLE 2.1: Types of Organic Compounds

Type of Compound Carbohydrates	Examples sugars, starches	Elements carbon, hydrogen, oxygen	Functions provides energy to cells, stores energy, forms body structures
Lipids	fats, oils	carbon, hydrogen, oxygen	stores energy, forms cell membranes, carries mes- sages
Proteins	enzymes, antibodies	carbon, hydrogen, oxygen, nitrogen, sulfur	helps cells keep their shape, makes up muscles, speeds up chemical reactions, carries messages and materials
Nucleic Acids	DNA, RNA	carbon, hydrogen, oxygen, nitrogen, phosphorus	contains instructions for proteins, passes instruc- tions from parents to off- spring, helps make pro- teins

Carbohydrates

Carbohydrates are the most common type of organic compound. A **carbohydrate** is an organic compound such as sugar or starch, and is used to store energy. Like most organic compounds, carbohydrates are built of small, repeating units that form bonds with each other to make a larger molecule. In the case of carbohydrates, the small, repeating units are called monosaccharides.

Lipids

A **lipid** is an organic compound such as fat or oil. Organisms use lipids to store energy, but lipids have other important roles as well. Lipids consist of repeating units called fatty acids. There are two types of fatty acids: saturated fatty acids and unsaturated fatty acids.

Proteins

A **protein** is an organic compound made up of small molecules called **amino acids**. There are 20 different amino acids commonly found in the proteins of living things. Small proteins may contain just a few hundred amino acids, whereas large proteins may contain thousands of amino acids.

Nucleic Acids

A **nucleic acid** is an organic compound, such as DNA or RNA, that is built of small units called nucleotides. Many nucleotides bind together to form a chain called a **polynucleotide**. The nucleic acid **DNA** (deoxyribonucleic acid) consists of two polynucleotide chains. The nucleic acid **RNA** (ribonucleic acid) consists of just one polynucleotide chain.

Questions

1. List two functions of organic compounds.

2. Which two categories of organic compounds store energy? Which of these organic compounds is more common?

3. What is a main difference between DNA and RNA?

4. Describe a difference between large and small proteins.

5. Why is carbon considered the essential element of life?

- b. A process that changes some chemical substances into others is a
 - a. chemical bond.
 - b. chemical reaction.
 - c. chemical equation.
 - d. chemical formula.
- c. The main difference between saturated and unsaturated fatty acids is
 - a. the amount of energy found in the fatty acid.
 - b. saturated fatty acids are liquids.
 - c. unsaturated fatty acids can be packed together very tightly.
 - d. the number of hydrogen atoms bonded to the carbon atoms.
- d. The function of proteins can include
 - a. helping cells keep their shape.
 - b. helping to destroy foreign substances.
 - c. speeding up biochemical reactions.
 - d. all of the above
- e. The characteristics of DNA includes which of the following?
 - a. DNA is made of nucleotides consisting of a sugar, a phosphate group, and a carbon base.
 - b. DNA is made of a single polynucleotide chain, which winds into a double helix.
 - c. DNA is how inherited characteristics are passed from one generation to the next.
 - d. all of the above
- f. Which category of organic compound is the major component of cell membranes?
 - a. carbohydrate
 - b. lipid
 - c. protein
 - d. nucleic acid
- g. The cell wall of plants is made out of
 - a. starch.
 - b. glycogen.
 - c. cellulose.
 - d. chitin.
- h. The main element of organic compounds is
 - a. hydrogen.
 - b. oxygen.
 - c. nitrogen.
 - d. carbon.

Biochemical Reactions and Enzymes

Biochemical reactions are chemical reactions that take place inside the cells of living things. Biochemistry is a relatively new field that emerged at the interface of biology and chemistry. Its emergence shows that knowledge of chemistry as well as biology is needed to understand fully the life processes of organisms at the level of the cell. The sum of all the biochemical reactions in an organism is called **metabolism**. It includes both exothermic and endothermic reactions.

Types of Biochemical Reactions

Exothermic reactions in organisms are called **catabolic reactions**. These reactions break down molecules into smaller units and release energy. An example of a catabolic reaction is the breakdown of glucose, which releases energy that cells need to carry out life processes. Endothermic reactions in organisms are called **anabolic reactions**. These reactions build up bigger molecules from smaller ones. An example of an anabolic reaction is the joining of amino acids to form a protein. Which type of reactions — catabolic or anabolic — do you think occur when your body digests food?

Enzymes

Most biochemical reactions in organisms need help in order to take place. Why is this the case? For one thing, temperatures are usually too low inside living things for biochemical reactions to occur quickly enough to maintain life. The concentrations of reactants may also be too low for them to come together and react. Where do the biochemical reactions get the help they need to proceed? The help comes from enzymes.

An **enzyme** is a protein that speeds up a biochemical reaction. An enzyme works by reducing the amount of activation energy needed to start the reaction. Less activation energy is needed when the correct enzyme is present than when it is not present.

Enzymes are involved in most biochemical reactions, and they do their job extremely well. A typical biochemical reaction could take several days to occur without an enzyme. With the proper enzyme, the same reaction can occur in just a split second! Without enzymes to speed up biochemical reactions, most organisms could not survive. The activities of enzymes depend on the temperature, ionic conditions, and the pH of the surroundings. Some enzymes work best at an acidic pH, while others work best in neutral environments.

Name	Class	Date	
	es from the text and answer		

Acids and Bases

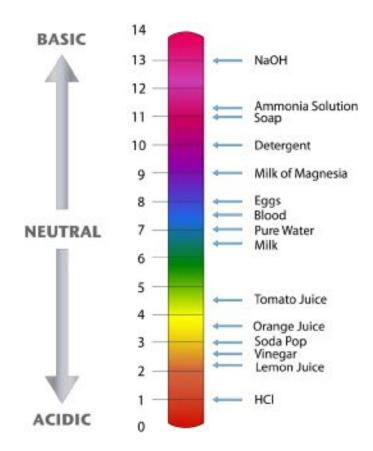

Water is the main ingredient of many solutions. A **solution** is a mixture of two or more substances that has the same composition throughout. Some solutions are acids and some are bases. To understand acids and bases, you need to know more about pure water. In pure water (such as distilled water), a tiny fraction of water molecules naturally break down to form ions. An ion is an electrically charged atom or molecule. The breakdown of water is represented by the chemical equation

$$2H_2O \rightarrow H_3O^+ + OH^-$$

The products of this reaction are a hydronium ion (H_3O^+) and a hydroxide ion (OH^-) . The hydroxide ion, which has

a negative charge, forms when a water molecule gives up a positively charged hydrogen ion (H⁺). The hydronium ion, which has positive charge, forms when another water molecule accepts the hydrogen ion.

Acidity and pH The concentration of hydronium ions in a solution is known as acidity. In pure water, the concentration of hydronium ions is very low; only about 1 in 10 million water molecules naturally breaks down to form a hydronium ion. As a result, pure water is essentially neutral. Acidity is measured on a scale called **pH**, as shown in the figure below. Pure water has a pH of 7, so the point of neutrality on the pH scale is 7.

pH Scale. The pH scale ranges from 0 to 14, with 7 being the point of neutrality. What is the pH of lemon juice? Of milk? (*Image courtesy of Edward Stevens, modified by CK-12 Foundation, and under the Creative Commons license CC-BY-SA 3.0.*)

Acids and Bases in Organisms

Acids and bases are important in living things because most enzymes can do their job only at a certain level of acidity. Cells secrete acids and bases to maintain the proper pH for enzymes to work. For example, every time you digest food, acids and bases are at work in your digestive system. Consider the enzyme pepsin, which helps break down proteins in the stomach. Pepsin needs an acidic environment to do its job, and the stomach secretes a strong acid that allows pepsin to work. However, when stomach contents enter the small intestine, the acid must be neutralized. This is because enzymes in the small intestine need a basic environment in order to work. An organ called the pancreas secretes a strong base into the small intestine, and this base neutralizes the acid.

Water and Life

The human body is about 70% water (not counting the water in body fat, which varies from person to person). The body needs all this water to function normally. Just why is so much water required by human beings and other organisms? Water can dissolve many substances that organisms need, and it is necessary for many biochemical reactions. The examples below are among the most important biochemical processes that occur in living things, but they are just two of many ways that water is involved in biochemical reactions.

• Photosynthesis — In this process, cells use the energy in sunlight to change carbon dioxide and water to glucose and oxygen. The reactions of photosynthesis can be represented by the chemical equation

$$6CO_2 + 6H_2O + Energy \rightarrow C_6H_{12}O_6 + 6O_2$$

• Cellular respiration — In this process, cells break down glucose in the presence of oxygen and release carbon dioxide, water, and energy. The reactions of cellular respiration can be represented by the chemical equation

$$C_6H_{12}O_6 + 6O_2 \rightarrow 6CO_2 + 6H_2O + Energy$$

Water is involved in many other biochemical reactions. As a result, just about all life processes depend on water. Clearly, life as we know it could not exist without water.

Questions

1. Describe the best environment for the enzyme pepsin.

2. Why is water so important for life?

3. Which is a stronger acid: lemon juice or soda pop? Why?

4. What is a hydronium ion? How does one form?

Two Types of Cells

There is another basic cell structure that is present in many but not all living cells: the nucleus. The **nucleus** of a cell is a structure in the cytoplasm that is surrounded by a membrane (the nuclear membrane) and contains DNA. Based on whether they have a nucleus, there are two basic types of cells: prokaryotic cells and eukaryotic cells.

Prokaryotic Cells

Prokaryotic cells are cells without a nucleus. The DNA in prokaryotic cells is in the cytoplasm rather than enclosed within a nuclear membrane. Prokaryotic cells are found in single-celled organisms, such as bacteria. Organisms with prokaryotic cells are called **prokaryotes**. They were the first type of organisms to evolve and are still the most

3.1. Introduction to Cells www.ck12.org

common organisms today.

Eukaryotic Cells

Eukaryotic cells are cells that contain a nucleus. Eukaryotic cells are usually larger than prokaryotic cells, and they are found mainly in multicellular organisms. Organisms with eukaryotic cells are called eukaryotes, and they range from fungi to people. Eukaryotic cells also contain other organelles besides the nucleus. An **organelle** is a structure within the cytoplasm that performs a specific job in the cell. Organelles called mitochondria, for example, provide energy to the cell, and organelles called vacuoles store substances in the cell. Organelles allow eukaryotic cells to carry out more functions than prokaryotic cells can.

Viruses: Prokaryotes or Eukaryotes?

Viruses are tiny particles that may cause disease. Human diseases caused by viruses include the common cold and flu. Do you think viruses are prokaryotes or eukaryotes? The answer may surprise you. Viruses are not cells at all, so they are neither prokaryotes nor eukaryotes.

Viruses contain DNA but not much else. They lack the other parts shared by all cells, including a plasma membrane, cytoplasm, and ribosomes. Therefore, viruses are not cells, but are they alive? All living things not only have cells; they are also capable of reproduction. Viruses cannot reproduce by themselves. Instead, they infect living hosts, and use the hosts' cells to make copies of their own DNA. For these reasons, most scientists do not consider viruses to be living things.

Plasma Membrane

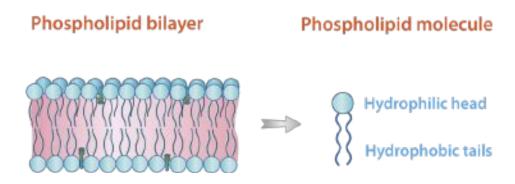

The plasma membrane forms a barrier between the cytoplasm inside the cell and the environment outside the cell. It protects and supports the cell and also controls everything that enters and leaves the cell. It allows only certain substances to pass through, while keeping others in or out. The ability to allow only certain molecules in or out of the cell is referred to as selective permeability or semipermeability. To understand how the plasma membrane controls what crosses into or out of the cell, you need to know its composition.

Read these passages from the text and answer the questions that follow.

3.2. Cell Structures www.ck12.org

Phospholipid Bilayer

The plasma membrane is composed mainly of phospholipids, which consist of fatty acids and alcohol. The phospholipids in the plasma membrane are arranged in two layers, called a phospholipid bilayer. As shown in the figure below, each phospholipid molecule has a head and two tails. The head "loves" water (hydrophilic) and the tails "hate" water (hydrophobic). The water-hating tails are on the interior of the membrane, whereas the water-loving heads point outwards, toward either the cytoplasm or the fluid that surrounds the cell. Molecules that are hydrophobic can easily pass through the plasma membrane, if they are small enough, because they are water-hating like the interior of the membrane. Molecules that are hydrophilic, on the other hand, cannot pass through the plasma membrane — at least not without help — because they are water-loving like the exterior of the membrane.

The phospholipid bilayer consists of two layers of phospholipids (left), with a hydrophobic, or water-hating, interior and a hydrophilic, or water-loving, exterior. A single phospholipid molecule is depicted on the right. (*Image courtesy of CK-12 Foundation and under the Creative Commons license CC-BY-NC-SA 3.0.*)

Other Molecules in the Plasma Membrane

The plasma membrane also contains other molecules, primarily other lipids and proteins. The green molecules in the figure above, for example, are the lipid cholesterol. Molecules of cholesterol help the plasma membrane keep its shape. Many of the proteins in the plasma membrane assist other substances in crossing the membrane.

Extensions of the Plasma Membrane

The plasma membrane may have extensions, such as whip-like flagella or brush-like cilia. In single-celled organisms, the membrane extensions may help the organisms move. In multicellular organisms, the extensions have other functions. For example, the cilia on human lung cells sweep foreign particles and mucus toward the mouth and nose.

Questions

1. What is the plasma membrane?

3. Discuss why the plasma membrane must be a bilayer.

4. What are some of the "other" molecules in the plasma membrane? Describe their function.

5. What are cilia and flagella?

Name	Class Date

Passive Transport

Passive transport occurs when substances cross the plasma membrane without any input of energy from the cell. No energy is needed because the substances are moving from an area where they have a higher concentration to an area where they have a lower concentration. Concentration refers to the number of particles of a substance per unit of volume. The more particles of a substance in a given volume, the higher the concentration. A substance always moves from an area where it is more concentrated to an area where it is less concentrated. It's a little like a ball rolling down a hill. It goes by itself without any input of extra energy.

Read these passages from the text and answer the questions that follow.

Simple Diffusion

Diffusion is the movement of a substance across a membrane, due to a difference in concentration, without any help from other molecules. The substance simply moves from the side of the membrane where it is more concentrated to the side where it is less concentrated. Substances that can squeeze between the lipid molecules in the plasma membrane by simple diffusion are generally very small, hydrophobic molecules, such as molecules of oxygen and carbon dioxide.

Osmosis

Osmosis is a special type of diffusion — the diffusion of water molecules across a membrane. Like other molecules, water moves from an area of higher concentration to an area of lower concentration. Water moves in or out of a cell until its concentration is the same on both sides of the plasma membrane.

Facilitated Diffusion

Water and many other substances cannot simply diffuse across a membrane. Hydrophilic molecules, charged ions, and relatively large molecules, such as glucose, all need help with diffusion. The help comes from special proteins in the membrane known as **transport proteins**. Diffusion with the help of transport proteins is called **facilitated diffusion**. There are several types of transport proteins, including channel proteins and carrier proteins.

- Channel proteins form pores, or tiny holes, in the membrane. This allows water molecules and small ions to pass through the membrane without coming into contact with the hydrophobic tails of the lipid molecules in the interior of the membrane.
- Carrier proteins bind with specific ions or molecules, and in doing so, they change shape. As carrier proteins change shape, they carry the ions or molecules across the membrane.

Introduction

All living things need **energy**, which is defined as the ability to do work. You can often see energy at work in living things — a bird flies through the air, a firefly glows in the dark, a dog wags its tail. These are obvious ways that living things use energy, but living things constantly use energy in less obvious ways as well.

Why Living Things Need Energy

Inside every cell of all living things, energy is needed to carry out life processes. Energy is required to break down and build up molecules and to transport molecules across plasma membranes. All life's work needs energy. A lot of energy is also simply lost to the environment as heat. The story of life is a story of energy flow — its capture, its change of form, its use for work, and its loss as heat. Energy, unlike matter, cannot be recycled, so organisms require a constant input of energy. Life runs on chemical energy. Where do living organisms get this chemical energy?

How Organisms Get Energy: Autotrophs and Heterotrophs

The chemical energy that organisms need comes from food. **Food** consists of organic molecules that store energy in their chemical bonds. In terms of obtaining food for energy, there are two types of organisms: autotrophs and heterotrophs.

Autotrophs

Autotrophs are organisms that make their own food. Most autotrophs use the energy in sunlight to make food in a process called **photosynthesis**. Only three types of organisms — plants, algae, and some bacteria — can make food through photosynthesis.

Autotrophs are also called **producers**. They produce food not only for themselves but for all other living things as well (which are known as consumers). This is why autotrophs form the basis of food chains.

Heterotrophs

Heterotrophs are living things that cannot make their own food. Instead, they get their food by consuming other organisms, which is why they are also called **consumers**. They may consume autotrophs or other heterotrophs. Heterotrophs include all animals and fungi and many single-celled organisms. What do you think would happen to consumers if all producers were to vanish from Earth?

Questions

1. What is energy? Give an example of how energy is used in a living organism.

2. Distinguish between autotrophs and heterotrophs.

3. Determine if the following are autotrophs or heterotrophs: (a) a giant redwood tree, (b) a spider, (c) a rose bush, (d) a mushroom, (e) a blue whale.

4.1. Energy for Life www.ck12.org

4. How is energy used in a cell?

5. Why are autotrophs considered the basis of food chains?

Lesson 4.1: Multiple Choice

Name_____ Class____ Date____

Circle the letter of the correct choice.

- a. Photosynthesis
 - a. uses the energy in sunlight to make food.
 - b. uses the glucose in sunlight to make food.
 - c. uses the energy in sunlight to make ATP.
 - d. breaks down glucose to form ATP.
- b. Which of the following autotrophs is also a producer?
 - a. a maple tree
 - b. the blue-green bacteria known as cyanobacteria
 - c. Laurencia, a marine genus of Red Algae from Hawaii.
 - d. All of the above are producers.

- c. In the food chain grass \rightarrow grasshopper \rightarrow snake \rightarrow hawk, which organism(s) are the heterotrophs?
 - a. the grass
 - b. the grass and grasshopper
 - c. the hawk
 - d. the grasshopper, snake, and hawk
- d. Which of the following statements is true about glucose and ATP? (1) Glucose is made during photosynthesis.
 - (2) The energy in sunlight is temporarily stored in glucose before it is transferred to ATP. (3) ATP is the energy-carrying molecule that cells use for energy. (4) The processes that make ATP and glucose also recycle oxygen in Earth's atmosphere.
 - a. statement 1 only
 - b. statements 2 and 3 only
 - c. statements 1, 2, and 3 only
 - d. All 4 statements are correct.
- e. Photosynthesis can be described as the process that
 - a. uses carbon dioxide and water, in the presence of sunlight, to produce food (glucose) and oxygen.
 - b. uses glucose and oxygen to produce energy for the cell (ATP), releasing carbon dioxide and water.

Date

- c. uses glucose and oxygen, in the presence of sunlight, to make ATP.
- d. uses carbon dioxide and water, in the presence of sunlight, to produce ATP and oxygen.
- f. Which statement best describes the relationship between a consumer and a producer?
 - a. A lion eating an antelope.
 - b. A caterpillar eating a leaf.
 - c. A snake eating a rat.
 - d. A flower absorbing sunlight.
- g. Which of the following statements is true?
 - a. The products of photosynthesis are the reactants of cellular respiration.
 - b. The products of cellular respiration are the reactants of photosynthesis.
 - c. Both statements are true.
 - d. Neither statement is true.
- h. The correct chemical formula for photosynthesis (in the presence of sunlight) is
 - a. $6CO_2 + 6O_2 \rightarrow C_6H_{12}O_6 + 6H_2O$.
 - b. $6CO_2 + 6H_2O \rightarrow C_6H_{12}O_6 + 6O_2$.
 - c. $C_6H_{12}O_6 + 6O_2 \rightarrow 6CO_2 + 6H_2O$
 - d. $C_6H_{12}O_6 + 6CO_2 \rightarrow 6O_2 + 6H_2O$

Lesson 4.2: Critic	cal Reading	
Name	Class	Date

Photosynthesis Stage I: The Light Reactions

The first stage of photosynthesis is called the light reactions. During this stage, light is absorbed and transformed to chemical energy in the bonds of NADPH and ATP. You can read about this process below.

Steps of the Light Reactions

The light reactions occur in several steps, all of which take place in the thylakoid membrane.

• Step 1: Units of sunlight, called photons, strike a molecule of chlorophyll in photosystem II of the thylakoid membrane. The light energy is absorbed by two electrons (2 e⁻) in the chlorophyll molecule, giving them enough energy to leave the molecule.

- Step 2: At the same time, enzymes in the thylakoid membrane use light energy to split apart a water molecule. This produces:
 - two electrons (2e⁻). These electrons replace the two electrons that were lost from the chlorophyll molecule in Step 1.
 - an atom of oxygen (O). This atom combines with another oxygen atom to produce a molecule of oxygen gas (O₂), which is released as a waste product.
 - two hydrogen ions (2H⁺). The hydrogen ions, which are positively charged, are released inside the membrane in the thylakoid interior space.
- Step 3: The two excited electrons from Step 1 contain a great deal of energy, so, like hot potatoes, they need something to carry them. They are carried by a series of electron-transport molecules, which make up an **electron transport chain**. The two electrons are passed from molecule to molecule down the chain. As this happens, their energy is captured and used to pump more hydrogen ions into the thylakoid interior space.
- Step 4: When the two electrons reach photosystem I, they are no longer excited. Their energy has been captured and used, and they need more energy. They get energy from light, which is absorbed by chlorophyll in photosystem I. Then, the two re-energized electrons pass down another electron transport chain.
- Step 5: Enzymes in the thylakoid membrane transfer the newly re-energized electrons to a compound called NADP⁺. Along with a hydrogen ion, this produces the energy-carrying molecule NADPH. This molecule is needed to make glucose in the Calvin cycle.
- Step 6: By now, there is a greater concentration of hydrogen ions and positive charge in the thylakoid interior space. This difference in concentration and charge creates what is called a chemiosmotic gradient. It causes hydrogen ions to flow back across the thylakoid membrane to the stroma, where their concentration is lower. Like water flowing through a hole in a dam, the hydrogen ions have energy as they flow down the chemiosmotic gradient. The enzyme ATP synthase acts as a channel protein and helps the ions cross the membrane. ATP synthase also uses their energy to add a phosphate group (Pi) to a molecule of ADP, producing a molecule of ATP. The energy in ATP is needed for the Calvin cycle.

4.	What is an e	electron tran	sport chain?	What is its	role during	these light	reactions?

5. How is ATP made during the light reactions?

Lesson 4.2: Multiple Choice

Name_____ Class____ Date____

Circle the letter of the correct choice.

- a. Most autotrophs make "food" through the process of
 - a. cellular respiration.
 - b. chemosynthesis.
 - c. homeostasis.
 - d. photosynthesis.
- b. The correct sequence of events in the light reactions is
 - a. absorption of sunlight, electrons flow down the electron transport chain, ATP is made, NADPH is made.
 - b. absorption of sunlight, splitting of water, electrons flow down the electron transport chain, ATP is made.
 - c. electrons flow down the electron transport chain, NADPH is made, ATP is made, water is split.
 - d. absorption of sunlight, electrons flow down the electron transport chain, NADPH is made, water is split.

c. The Calvin cycle occurs

- a. in the granum of the thylakoid membranes of the chloroplast.
- b. in the stroma surrounding the inner membrane of the chloroplast.
- c. in the stroma surrounding the thylakoid membranes of the chloroplast.
- d. in the granum inside the inner membrane of the chloroplast.

d. By the end of the light reactions, energy from sunlight

- a. has been stored in chemical bonds of NADPH and ATP.
- b. has been transferred to glucose.
- c. has entered the Calvin cycle.
- d. is ready for use in the cell.

e. ATP synthase is

- a. both an enzyme that makes ATP and a channel protein, and helps hydrogen ions cross the thylakoid membrane.
- b. both an enzyme that makes ATP and a channel protein, and helps hydrogen ions cross the chloroplast inner membrane.
- c. both an enzyme that makes ATP and a carrier protein, and helps hydrogen ions cross the thylakoid membrane.
- d. both an enzyme that makes ATP and a carrier protein, and helps hydrogen ions cross the chloroplast inner membrane.

f. Essentially, the oxygen we breathe is

- a. necessary for the light reactions to proceed.
- b. a waste product of photosynthesis.
- c. a reactant of the Calvin cycle.
- d. essential for the homeostasis of the plant cell.

g. The Calvin cycle

- a. starts with the molecule RuBP.
- b. uses the energy in ATP and NADPH from the light reactions.
- c. turns twice to produce one molecule of glucose.
- d. all of the above
- h. How do bacteria that live deep below the ocean's surface make food?
 - a. by photosynthesis
 - b. by chemosynthesis
 - c. by cellular respiration
 - d. They eat other organisms.

Cellular Respiration Stage III: Electron Transport

Electron transport is the final stage of aerobic respiration. In this stage, energy from NADH and FADH₂, which result from the Krebs cycle, is transferred to ATP. Can you predict how this happens? (*Hint:* How does electron transport occur in photosynthesis?)

Transporting Electrons

High-energy electrons are released from NADH and FADH₂, and they move along electron transport chains, like those used in photosynthesis. The electron transport chains are on the inner membrane of the mitochondrion. As the high-energy electrons are transported along the chains, some of their energy is captured. This energy is used to

pump hydrogen ions (from NADH and FADH₂) across the inner membrane, from the matrix into the intermembrane space.

Making ATP

The pumping of hydrogen ions across the inner membrane creates a greater concentration of the ions in the intermembrane space than in the matrix. This chemiosmotic gradient causes the ions to flow back across the membrane into the matrix, where their concentration is lower. ATP synthase acts as a channel protein, helping the hydrogen ions cross the membrane. It also acts as an enzyme, forming ATP from ADP and inorganic phosphate. After passing through the electron-transport chain, the "spent" electrons combine with oxygen to form water. This is why oxygen is needed; in the absence of oxygen, this process cannot occur.

How Much ATP?

You have seen how the three stages of aerobic respiration use the energy in glucose to make ATP. How much ATP is produced in all three stages? Glycolysis produces 2 ATP molecules, and the Krebs cycle produces 2 more. Electron transport begins with several molecules of NADH and FADH₂ from the Krebs cycle and transfers their energy into as many as 34 more ATP molecules. All told, then, up to 38 molecules of ATP can be produced from just one molecule of glucose in the process of aerobic respiration.

Questions

1. In photosynthesis, electron	n transport comes at the	beginning of the process.	Where does electron	transport occur
during cellular respiration?				

2. What is the role of the electron transport chain in cellular respiration?

3. Why is the role of oxygen in cellular respiration?

4. Describe ATP synthase and its role.

5. Summarize how up to 38 molecules of ATP are produced for each glucose molecule.

Lesson 4.3: Multiple Choice

Name	Class	Date	
1 141116	Ciass	Date	

Circle the letter of the correct choice.

- a. Glycolysis
 - a. uses 2 ATPs and makes 2 ATPs, 2 NADHs, and 2 pyruvates.
 - b. uses 2 ATPs and makes 4 ATPs, 2 NADHs, and 2 pyruvates.
 - c. uses 4 ATPs and makes 2 ATPs, 2 NADHs, and 2 pyruvates.
 - d. uses 2 ATPs and makes 4 ATPs, 4 NADHs, and 2 pyruvates.
- b. Cellular respiration in the presence of oxygen is called
 - a. anaerobic respiration.
 - b. glycolysis.
 - c. aerobic respiration.
 - d. oxygen respiration.
- c. The correct order of stages of cellular respiration is
 - a. glycolysis the Calvin cycle electron transport.
 - b. the light reactions glycolysis the Krebs cycle.
 - c. glycolysis the Krebs cycle electron transport.
 - d. electron transport glycolysis the Krebs cycle.
- d. Where are the electron transport chains of cellular respiration located?
 - a. in the inner membrane of the mitochondrion
 - b. in the matrix of the mitochondrion
 - c. in the intermembrane space of the mitochondrion

- d. in the outer membrane of the mitochondrion
- e. The final electron acceptor at the end of cellular respiration is
 - a. hydrogen.
 - b. oxygen.
 - c. water.
 - d. ATP synthase.
- f. The chemical formula of cellular respiration is
 - a. $6CO_2 + 6H_2O \rightarrow C_6H_{12}O_6 + 6O_2$.
 - b. $C_6H_{12}O_6 + O_2 \rightarrow CO_2 + H_2O$.
 - c. $CO_2 + H_2O \rightarrow C_6H_{12}O_6 + O_2$.
 - d. $C_6H_{12}O_6 + 6O_2 \rightarrow 6CO_2 + 6H_2O$.
- g. The chemiosmotic gradient of cellular respiration is an
 - a. ion gradient made by the pumping of hydrogen ions across the inner membrane using the energy of electrons as they are transported down the electron transport chain.
 - b. ion gradient made by the pumping of hydrogen ions across the outer membrane using the energy of electrons as they are transported down the electron transport chain.
 - c. ion gradient made by the pumping of oxygen ions across the inner membrane using the energy of electrons as they are transported down the electron transport chain.
 - d. ion gradient made by the diffusion of hydrogen ions across the inner membrane using the energy of electrons as they are transported down the electron transport chain.
- h. In the presence of oxygen, one glucose molecule has the energy to make up to
 - a. 4 FADH₂.
 - b. 12 NADH.
 - c. 38 ATP.
 - d. all of the above

Fermentation

An important way of making ATP without oxygen is called **fermentation**. It involves glycolysis but not the other two stages of aerobic respiration. Many bacteria and yeasts carry out fermentation. People use these organisms to make yogurt, bread, wine, and biofuels. Human muscle cells also use fermentation. This occurs when muscle cells cannot get oxygen fast enough to meet their energy needs through aerobic respiration. There are two types of fermentation: lactic acid fermentation and alcoholic fermentation. Both types of are described below.

Lactic Acid Fermentation

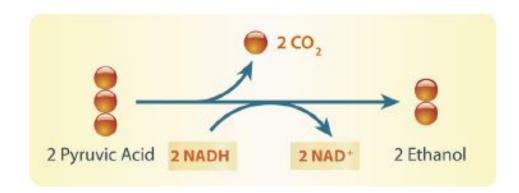

In lactic acid fermentation, pyruvic acid from glycolysis changes to lactic acid. In the process, NAD⁺ forms

from NADH. NAD⁺, in turn, lets glycolysis continue. This results in additional molecules of ATP. This type of fermentation is carried out by the bacteria in yogurt. It is also used by your own muscle cells when you work them hard and fast.

Did you ever run a race and notice that your muscles feel tired and sore afterward? This is because your muscle cells used lactic acid fermentation for energy. This causes lactic acid to build up in the muscles. It is the buildup of lactic acid that makes the muscles feel tired and sore.

Alcoholic Fermentation

In **alcoholic fermentation**, pyruvic acid changes to alcohol and carbon dioxide. NAD⁺ also forms from NADH, allowing glycolysis to continue making ATP. This type of fermentation is carried out by yeasts and some bacteria. It is used to make bread, wine, and biofuels.

Alcoholic fermentation produces ethanol and NAD⁺. The NAD⁺ allows glycolysis to continue making ATP. (*Image courtesy of CK-12 Foundation and under the Creative Commons license CC-BY-NC-SA 3.0.*)

Have your parents ever put corn in the gas tank of their car? They did if they used gas containing ethanol. Ethanol is produced by alcoholic fermentation of the glucose in corn or other plants. This type of fermentation also explains why bread dough rises. Yeasts in bread dough use alcoholic fermentation and produce carbon dioxide gas. The gas forms bubbles in the dough, which cause the dough to expand. The bubbles also leave small holes in the bread after it bakes, making the bread light and fluffy.

Questions

1. What is fermentation?

3. Both lactic acid fermentation and alcoholic fermentation begin with the same molecule. What is that molecule and where did it come from?

4. Why is bread light and fluffy?

5. Why do your muscles get sore after intense activity?

The Cell Cycle

Cell division is just one of several stages that a cell goes through during its lifetime. The **cell cycle** is a repeating series of events, including growth, DNA synthesis, and cell division. The cell cycle in prokaryotes is quite simple: the cell grows, its DNA replicates, and the cell divides. In eukaryotes, the cell cycle is more complicated.

Eukaryotic Cell Cycle

The diagram in the figure below represents the cell cycle of a eukaryotic cell. As you can see, the eukaryotic cell cycle has several phases. The mitosis phase (M) actually includes both mitosis and cytokinesis. This is when the

nucleus and then the cytoplasm divide. The other three phases (G1, S, and G2) are generally grouped together as **interphase**. During interphase, the cell grows, performs routine life processes, and prepares to divide. These phases are discussed below.

Eukaryotic Cell Cycle. This diagram represents the cell cycle in eukaryotes. The G1, S, and G2 phases make up interphase (I). The M phase includes mitosis and cytokinesis. After the M phase, two cells result. (*Image courtesy of CK-12 Foundation and under the Creative Commons license CC-BY-NC-SA 3.0.*)

Interphase

Interphase of the eukaryotic cell cycle can be subdivided into the following three phases, which are represented in the figure above:

- Growth Phase 1 (G1): During this phase, the cell grows rapidly, while performing routine metabolic processes. It also makes proteins needed for DNA replication and copies some of its organelles in preparation for cell division. A cell typically spends most of its life in this phase.
- Synthesis Phase (S): During this phase, the cell's DNA is copied in the process of DNA replication.
- Growth Phase 2 (G2): During this phase, the cell makes final preparations to divide. For example, it makes additional proteins and organelles.

Cancer and the Cell Cycle

Cancer is a disease that occurs when the cell cycle is no longer regulated. This may happen because a cell's DNA becomes damaged. Damage can occur because of exposure to hazards such as radiation or toxic chemicals. Cancerous cells generally divide much faster than normal cells. They may form a mass of abnormal cells called a **tumor**. The rapidly dividing cells take up nutrients and space that normal cells need. This can damage tissues and organs and eventually lead to death.

Questions

1. What is the cell cycle?

2. What are the phases of the eukaryotic cell cycle?

3. In which phase does a cell spend most of its life? What happens during this phase?

4. What is cancer? What may cause cancer to occur?

5. What is the S phase? What happens during this phase?

Lesson 5.1: Multiple Choice

Name Class Date	
-----------------	--

Circle the letter of the correct choice.

- a. Which cells undergo cell division?
 - a. prokaryotic cells only
 - b. eukaryotic cells only
 - c. cancer cells only
 - d. both prokaryotic and eukaryotic cells
- b. Cell division in eukaryotic cells is a complex process because of
 - a. the multiple chromosomes.
 - b. the nucleus.
 - c. the many organelles.
 - d. all of the above
- c. Most routine metabolic processes occur during which phase of the cell cycle?
 - a. growth phase 1
 - b. the S phase
 - c. growth phase 2
 - d. the M phase
- d. The correct order of the eukaryotic cell cycle is
 - a. $G1 \rightarrow G2 \rightarrow S \rightarrow M$.
 - b. $S \rightarrow G1 \rightarrow G2 \rightarrow M$.
 - c. $M \rightarrow G1 \rightarrow S \rightarrow G2$.
 - d. $G1 \rightarrow S \rightarrow G2 \rightarrow M$.
- e. The correct order of prokaryotic cell division is
 - a. cytokinesis \rightarrow DNA replication \rightarrow chromosome segregation.
 - b. DNA replication \rightarrow chromosome segregation \rightarrow cytokinesis.
 - c. growth \rightarrow DNA replication \rightarrow mitosis.
 - d. DNA replication \rightarrow mitosis \rightarrow cytokinesis.
- f. Which cell cycle checkpoint determines whether the DNA has been replicated correctly?
 - a. the cell growth checkpoint
 - b. the DNA synthesis checkpoint
 - c. the mitosis checkpoint
 - d. the G2 checkpoint
- g. What happens during mitosis?
 - a. The nucleus of the cell divides.
 - b. The cytoplasm of the cell divides.
 - c. The cell divides.
 - d. The DNA replicates.
- h. Cell division in prokaryotic cells is called
 - a. binary fission.
 - b. binary fusion.
 - c. mitosis.
 - d. cytokinesis.

Chromosomes

Chromosomes are coiled structures made of DNA and proteins. Chromosomes are the form of the genetic material of a cell during cell division. During other phases of the cell cycle, DNA is not coiled into chromosomes. Instead, it exists as a grainy material called **chromatin**.

Chromatids and the Centromere

DNA condenses and coils into the familiar X-shaped form of a chromosome only after it has replicated, as seen in the figure below. Because DNA has already replicated, each chromosome actually consists of two identical copies.

The two copies are called sister **chromatids**. They are attached to one another at a region called the **centromere**.

Chromosome. After DNA replicates, it forms chromosomes like the one shown here. (*Image copyright Cre8tive Images*, 2010. Used under license from Shutterstock.com. Text added by CK-12 Foundation.)

Chromosomes and Genes

The DNA of a chromosome is encoded with genetic instructions for making proteins. These instructions are organized into units called **genes**. Most genes contain the instructions for a single protein. There may be hundreds or even thousands of genes on a single chromosome.

Human Chromosomes

Human cells normally have two sets of chromosomes, one set inherited from each parent. There are 23 chromosomes in each set, for a total of 46 chromosomes per cell. Each chromosome in one set is matched by a chromosome of the same type in the other set, so there are actually 23 pairs of chromosomes per cell. Each pair consists of chromosomes of the same size and shape that also contain the same genes. The chromosomes in a pair are known as **homologous chromosomes**.

Questions

1. What is a chromosome? What is it made out of?

2. What are homologous chromosomes? How many homologous pairs are in a human cell?

3. What is the main difference between chromatin and chromosomes?
4. Why do chromosomes look like an "X"?
5. What is a gene?
Lesson 5.2: Multiple Choice

Name_____ Class____ Date____

Circle the letter of the correct choice.

- a. Why is it necessary for the DNA to replicate prior to cell division?
 - a. so that each daughter cell will have 23 chromosomes
 - b. so that each daughter cell will have a complete copy of the genetic material
 - c. so that each daughter cell will have 46 homologous chromosomes
 - d. so that each daughter cell will have 2 sister chromatids
- b. Why do chromosomes have an X-shape?
 - a. because they are made of two sister chromatins
 - b. because they are made of two sister centromeres
 - c. because they are made of two sister chromosomes

- d. because they are made of two sister chromatids
- c. Chromosomes form during what part of the cell cycle?
 - a. prophase of mitosis
 - b. the end of the G2 phase
 - c. right after S phase and DNA replication
 - d. during cytokinesis
- d. The correct order of phases during mitosis is
 - a. $telophase \rightarrow prophase \rightarrow metaphase \rightarrow anaphase$
 - b. $prophase \rightarrow anaphase \rightarrow metaphase \rightarrow telophase$
 - $c. \ prophase {\rightarrow} metaphase {\rightarrow} telophase {\rightarrow} anaphase$
 - d. prophase \rightarrow metaphase \rightarrow anaphase \rightarrow telophase
- e. How many chromosomes are in a normal human cell?
 - a. 23
 - b. 32
 - c. 46
 - d. 64
- f. When do the sister chromatids line up at the equator of the cell?
 - a. metaphase
 - b. anaphase
 - c. prophase
 - d. telophase
- g. Which of the following statements concerning cytokinesis is correct? (1) cytokinesis occurs in both prokaryotes and eukaryotes, (2) cytokinesis is when the cytoplasm splits in two, (3) in plant cells, cytokinesis involves the formation of a cell plate.
 - a. 1 only
 - b. 2 only
 - c. 1 and 2
 - d. 1, 2, and 3
- h. During which phase of mitosis do the sister chromatids separate?

Class

- a. prophase
- b. telophase
- c. anaphase
- d. metaphase

Lesson 5.2:	Vocabulary

Meiosis

The process that produces haploid gametes is meiosis. **Meiosis** is a type of cell division in which the number of chromosomes is reduced by half. It occurs only in certain special cells of the organisms. During meiosis, homologous chromosomes separate, and the haploid cells that form have only one chromosome from each pair. Two cell divisions occur during meiosis, and a total of four haploid cells are produced. The two cell divisions are called meiosis I and meiosis II.

Phases of Meiosis

Meiosis I begins after DNA replicates during interphase. In both meiosis I and meiosis II, cells go through the same

four phases as mitosis. However, there are important differences between meiosis I and mitosis.

Meiosis I

- a. Prophase I: The nuclear envelope begins to break down, and the chromosomes condense. Centrioles start moving to opposite poles of the cell, and a spindle begins to form. Importantly, homologous chromosomes pair up, which is unique to prophase I. In prophase of mitosis and meiosis II, homologous chromosomes do not form pairs in this way.
- b. Metaphase I: Spindle fibers attach to the paired homologous chromosomes. The paired chromosomes line up along the equator of the cell. This occurs only in metaphase I. In metaphase of mitosis and meiosis II, it is sister chromatids that line up along the equator of the cell.
- c. Anaphase I: Spindle fibers shorten, and the chromosomes of each homologous pair start to separate from each other. One chromosome of each pair moves toward one pole of the cell, and the other chromosome moves toward the opposite pole.
- d. Telophase I and Cytokinesis: The spindle breaks down, and new nuclear membranes form. The cytoplasm of the cell divides, and two haploid daughter cells result. The daughter cells each have a random assortment of chromosomes, with one from each homologous pair. Both daughter cells go on to meiosis II.

Meiosis II

- a. Prophase II: The nuclear envelope breaks down and the spindle begins to form in each haploid daughter cell from meiosis I. The centrioles also start to separate.
- b. Metaphase II: Spindle fibers line up the sister chromatids of each chromosome along the equator of the cell.
- c. Anaphase II: Sister chromatids separate and move to opposite poles.
- d. Telophase II and Cytokinesis: The spindle breaks down, and new nuclear membranes form. The cytoplasm of each cell divides, and four haploid cells result. Each cell has a unique combination of chromosomes.

Questions

1. Define meiosis.

2. Is the DNA replicated after meiosis I? Why or why not?

3. Describe the main difference between metaphase I and metaphase II.

	3. Heredity is the science of genetics.
	4. In Mendel's initial experiments, white flowers disappeared after the first parental crosses.
	5. It was his knowledge of genes that allowed Mendel to interpret his data correctly.
	6. Having naturally light or dark skin is part of your phenotype.
	7. Different alleles account for much of the variation in the characteristics of organisms.
	8. Mendel showed that factors controlling different characteristics are inherited independently.
	9. Mendel came up with the idea that two factors control a characteristic, such as pod color.
	10. Mendel developed three laws of inheritance.
	11. The expression of an organism's phenotype produces its genotype.
	12. After he published his work, Mendel achieved great fame among scientists.
	13. Through his experiments, Mendel was able to prove some aspects of the blending theory of inheritance
	14. A <i>Dd</i> genotype has two different alleles.
	15. Flowers are the reproductive organs of plants.
Less	son 6.1: Critical Reading
Name	Class Date
Read t	these passages from the text and answer the questions that follow.

At first, Mendel experimented with just one characteristic at a time. He began with flower color. As shown in the figure below, Mendel cross-pollinated purple- and white-flowered parent plants. The parent plants in the experiments

Mendel's First Set of Experiments

are referred to as the P (for parent) generation.

This diagram shows Mendel's first experiment with pea plants. The F1 generation results from cross-pollination of two parent (P) plants. The F2 generation results from self-pollination of F1 plants. (Image courtesy of CK-12 Foundation and under the Creative Commons license CC-BY-NC-SA 3.0.)

F1 and F2 Generations

The offspring of the P generation are called the F1 (for filial, or "offspring") generation. As you can see from the figure above, all of the plants in the F1 generation had purple flowers. None of them had white flowers. Mendel wondered what had happened to the white-flower characteristic. He assumed some type of inherited factor produces white flowers and some other inherited factor produces purple flowers. Did the white-flower factor just disappear in the F1 generation? If so, then the offspring of the F1 generation — called the F2 generation — should all have purple flowers like their parents. To test this prediction, Mendel allowed the F1 generation plants to self-pollinate. He was surprised by the results. Some of the F2 generation plants had white flowers. He studied hundreds of F2 generation plants, and for every three purple-flowered plants, there was an average of one white-flowered plant.

Law of Segregation

Mendel did the same experiment for all seven characteristics. In each case, one value of the characteristic disappeared in the F1 plants and then showed up again in the F2 plants. And in each case, 75 percent of F2 plants had one value of the characteristic and 25 percent had the other value. Based on these observations, Mendel formulated his first law of inheritance. This law is called the **law of segregation**. It states that there are two factors controlling a given characteristic, one of which dominates the other, and these factors separate and go to different gametes when a parent reproduces.

Questions

1. What did Mendel do in his first experiment?

2. What was the outcome of the F1 generation in Mendel's first experiment?

3. What was the outcome of the F2 generation in Mendel's first experiment?

4. Did Mendel repeat his initial experiment with other characteristics? What were his results?

5. Explain the law of segregation. Discuss the reasoning Mendel used to develop this law.

Lesson 6.1: Multiple Choice

Name	Class	Date
------	-------	------

Circle the letter of the correct choice.

- a. Why did Mendel choose to work with the garden pea plant?
 - a. Because the pea plant is easy to work with.
 - b. Because pea plants are fast growing.
 - c. Because the pea plant has a number of characteristics, each with only two forms.
 - d. all of the above
- b. In Mendel's first experiment
 - a. the F1 displayed all purple-flowered plants.
 - b. the F1 displayed all white-flowered plants.
 - c. the F2 displayed all purple-flowered plants.
 - d. the F2 displayed half purple-flowered and half white-flowered plants.
- c. The law of independent assortment states that
 - a. two factors of the same characteristic separate into different gametes.
 - b. there are dominant and recessive factors.
 - c. factors controlling different characteristics are inherited independently of each other.
 - d. there are two factors that control inheritance.
- d. Looking at your dog will give information concerning
 - a. the dog's genotype.
 - b. the dog's phenotype.
 - c. the dog's recessive alleles.
 - d. the dog's heterozygous alleles.
- e. Which sentence is correct?
 - a. Different alleles of the same gene are located at the same locus on different homologous chromosomes.
 - b. Different alleles of the same gene are located at different loci on different homologous chromosomes.
 - c. Different genes of the same alleles are located at the same locus on different homologous chromosomes.
 - d. Different alleles of the same gene are located at different loci on the same chromosome.
- f. An Aa individual
 - a. has a homozygous genotype.
 - b. has a heterozygous phenotype.
 - c. has a heterozygous genotype.
 - d. has a homozygous phenotype.
- g. In Mendel's initial experiments, an example of the F2 generation would be
 - a. 75 round seed plants to 25 wrinkled seed plants
 - b. 75 green seed plants to 25 yellow seed plants
 - c. 75 white-flowered plants to 25 purple-flowered plants
 - d. all of the above
- h. Which of the following is part of the law of segregation? (1) there are two factors controlling a given characteristic, (2) one factor is dominant over the other factor, (3) the two factors separate into different gametes.
 - a. 1 and 2
 - b. 1 and 3

- c. 2 and 3
- d. 1, 2, and 3

Name	Class	Date
Read these passage	es from the text and answer	r the questions that follow.

Using a Punnett Square

A **Punnett square** is a chart that allows you to easily determine the expected percents of different genotypes in the offspring of two parents. An example of a Punnett square for pea plants is shown below. In this example, both parents are heterozygous for flower color (Bb). The gametes produced by the male parent are at the top of the chart,

and the gametes produced by the female parent are along the side. The different possible combinations of alleles in their offspring are determined by filling in the cells of the Punnett square with the correct letters (alleles).

Punnett Square. This Punnett square shows a cross between two heterozygotes. Do you know where each letter (allele) in all four cells comes from? (Image courtesy of CK-12 Foundation and under the Creative Commons license CC-BY-NC-SA 3.0.)

Predicting Offspring Genotypes

In the cross shown in the figure above, you can see that one out of four offspring (25 percent) has the genotype BB, one out of four (25 percent) has the genotype bb, and two out of four (50 percent) have the genotype Bb. These percents of genotypes are what you would expect in any cross between two heterozygous parents. Of course, when just four offspring are produced, the actual percents of genotypes may vary by chance from the expected percents. However, if you considered hundreds of such crosses and thousands of offspring, you would get very close to the expected results — just like tossing a coin.

Predicting Offspring Phenotypes

You can predict the percents of phenotypes in the offspring of this cross from their genotypes. *B* is dominant to *b*, so offspring with either the *BB* or *Bb* genotype will have the purple-flower phenotype. Only offspring with the *bb* genotype will have the white-flower phenotype. Therefore, in this cross, you would expect three out of four (75 percent) of the offspring to have purple flowers and one out of four (25 percent) to have white flowers. These are the same percents that Mendel got in his first experiment.

Questions

You may use Punnett squares to answer the following questions.

1. What are the percents of genotypes you would expect in any cross between two heterozygous parents? Use the letters B and b in your answer.

2. What are the percents of phenotypes you would expect in any cross between two heterozygous parents? Use the genotypes and phenotypes in the reading above.

3.	Predict the percents	of genotypes you	would expec	t in any c	ross between a	homozygous	dominant	parent a	and a
ho	mozygous recessive	parent.							

4. Predict the percents of phenotypes you would expect in any cross between a homozygous dominant parent and a homozygous recessive parent.

5. Predict the percents of genotypes and phenotypes you would expect in any cross between a heterozygous parent and a homozygous recessive parent.

Read t	hese passages from the text and answer the questions that follow.

DNA

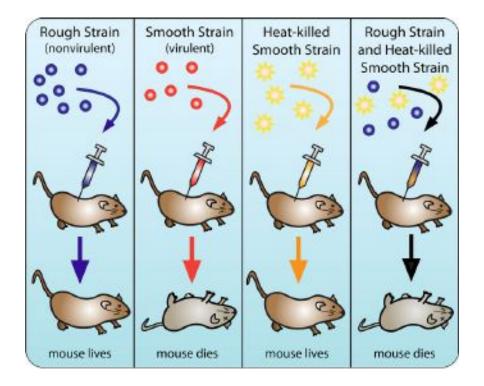

DNA is the genetic material in your cells. It was passed on to you from your parents and determines your characteristics. The discovery that DNA is the genetic material was another important milestone in molecular biology.

Griffith Searches for the Genetic Material

Many scientists contributed to the identification of DNA as the genetic material. In the 1920s, Frederick Griffith

7.1. DNA and RNA www.ck12.org

made an important discovery. He was studying two different strains of a bacterium, called R (rough) strain and S (smooth) strain. He injected the two strains into mice. The S strain (virulent) killed the mice, but the R strain (nonvirulent) did not (see the figure below). Griffith also injected mice with S-strain bacteria that had been killed by heat. As expected, the killed bacteria did not harm the mice. However, when the dead S-strain bacteria were mixed with live R-strain bacteria and injected, the mice died.

Griffith's Experimental Results. Griffith showed that a substance could be transferred to harmless bacteria and make them deadly. (*Image courtesy of CK-12 Foundation and under the Creative Commons license CC-BY-NC-SA 3.0.*)

Based on his observations, Griffith deduced that something in the killed S-strain was transferred to the previously harmless R-strain, making the R-strain deadly. What was that something? What type of substance could change the characteristics of the organism that received it?

Hershey and Chase Seal the Deal

The conclusion that DNA is the genetic material was not widely accepted at first. It had to be confirmed by other research. In the 1950s, Alfred Hershey and Martha Chase did experiments with viruses and bacteria. Viruses are not cells. They are basically DNA inside a protein coat. To reproduce, a virus must insert its own genetic material into a cell (such as a bacterium). Then it uses the cell's machinery to make more viruses. The researchers used different radioactive elements to label the DNA and proteins in viruses. This allowed them to identify which molecule the viruses inserted into bacteria. DNA was the molecule they identified. This confirmed that DNA is the genetic material.

Questions

1. In Griffith's experiments, what killed the mice?

2. Why did the rough strain and heat-killed smooth strain kill the mice?

3. Why are viruses not considered cells?

4. What were the results of Hershey and Chase's experiment?

5. The term given to Griffith's observations is **transformation.** Why do you think that term is appropriate?

7.1. DNA and RNA www.ck12.org

Lesson 7.1: Multiple Choice

Name	Class	Date
------	-------	------

Circle the letter of the correct choice.

- a. The order of experiments proving that DNA is the genetic material is
 - a. Avery \rightarrow Griffith \rightarrow Hershey and Chase.
 - b. Hershey and Chase \rightarrow Griffith \rightarrow Avery.
 - c. Griffith \rightarrow Avery \rightarrow Hershey and Chase.
 - d. Griffith \rightarrow Hershey and Chase \rightarrow Avery.
- b. Chargaff's rules state that
 - a. the amount of adenine equals the amount of thymine.
 - b. the amount of adenine equals the amount of guanine.
 - c. the amount of thymine equals the amount of guanine.
 - d. the amount of cytosine equals the amount of thymine.
- c. Which of the following statements concerning DNA is correct? (1) DNA contains instructions for all the proteins your body makes. (2) The shape of DNA is a double helix. (3) The central dogma of molecular biology states RNA → DNA → Protein.
 - a. 1 only
 - b. 1 and 2
 - c. 2 and 3
 - d. 1, 2, and 3
- d. The structure of DNA was identified by
 - a. Rosalind Franklin.
 - b. Erwin Chargaff.
 - c. Alfred Hershey and Martha Chase.
 - d. James Watson and Francis Crick.
- e. If one strand of DNA is CAGGTTACG, the opposite strand is
 - a. GTCCAATGC.
 - b. GTCCTTAGC.
 - c. CAGGTTACG.
 - d. GTCCTTACG.
- f. The subunits of DNA are nucleotides consisting of
 - a. a sugar, a carbon group, and a nitrogen-containing base.
 - b. a sugar, a phosphate group, and a nitrogen-containing base.
 - c. a sugar, a phosphate group, and an oxygen-containing base.
 - d. a lipid, a phosphate group, and a nitrogen-containing base.
- g. Differences between DNA and RNA include which of the following? (1) RNA consists of one nucleotide chain. (2) RNA contains the nitrogen base uracil instead of thymine. (3) RNA contains the sugar ribose instead of deoxyribose.
 - a. 1, 2, and 3
 - b. 1 and 2
 - c. 2 and 3
 - d. 2 only
- h. The types of RNA include

- a. messenger RNA.
- b. nuclear RNA.
- c. cytoplasmic RNA.
- d. all of the above

7.2 Protein Synthesis

Read these passages from the text and answer the questions that follow.

Name	Class	Date
Write true if the sta	ntement is true or false if t	the statement is false.
1. The proce	ess in which cells make pr	roteins is called protein expression.
2. Transcrip	tion takes place in three st	teps: initiation, elongation, and termination.
3. Splicing 1	removes introns from mRI	NA.
4. A codon o	can be described as a three	e-letter genetic "word."
5. UAG, UC	GA, AGU, and UAA are th	ne four stop codons
6. The antic	odon is part of each tRNA	A molecule.
7. Initiation	of transcription occurs wh	hen the enzyme, DNA polymerase, binds to the promoter of a gene.
8. All know	n living organisms, except	t some species of primitive bacteria, have the same genetic code.
9. Elongatio	n is the addition of amino	o acids to the mRNA strand.
10. Translat	ion always begins at an A	UG codon.
11. Many pr	roteins are modified in the	e Golgi apparatus after translation.
12. During t	ranslation, rRNA brings t	the amino acids into the ribosome.
13. Termina	tion of transcription occur	rs at a stop codon.
14. Transcri	ption uses DNA as a temp	plate to make an RNA molecule.
15. Translat	ion takes place in a riboso	ome.
Lesson 7.2: C	ritical Reading	
Name	Class	Date

The Genetic Code

How is the information in a gene encoded? The answer is the genetic code. The **genetic code** consists of the sequence of nitrogen bases — A, C, G, T (or U) — in a polynucleotide chain. The four bases make up the "letters" of the genetic code. The letters are combined in groups of three to form code "words," called **codons**. Each codon stands for (encodes) one amino acid, unless it codes for a start or stop signal. There are 20 common amino acids in proteins. There are 64 possible codons, more than enough to code for the 20 amino acids. The genetic code is shown in the FlexBook.

Reading the Genetic Code

www.ck12.org 7.2. Protein Synthesis

As shown in the Genetic Code figure (see Figure 7.8 in the FlexBook), the codon AUG codes for the amino acid methionine. This codon is also the start codon that begins translation. The start codon establishes the reading frame of mRNA. The reading frame is the way the letters are divided into codons. After the AUG start codon, the next three letters are read as the second codon. The next three letters after that are read as the third codon, and so on. The mRNA molecule is read, codon by codon, until a stop codon is reached. UAG, UGA, and UAA are all stop codons. They do not code for any amino acids.

Characteristics of the Genetic Code

The genetic code has a number of important characteristics.

- The genetic code is universal. All known living things have the same genetic code. This shows that all organisms share a common evolutionary history.
- The genetic code is unambiguous. Each codon codes for just one amino acid (or start or stop). What might happen if codons encoded more than one amino acid?
- The genetic code is redundant. Most amino acids are encoded by more than one codon. What might be an

\sim	
()111	estions
Qui	

advantage of having more than one codon for the same amino acid?	
Questions	
1. What is the genetic code?	
2. Explain the significance of an AUG codon.	
3. Why is the genetic code read three bases at a time?	

4.	"The genetic	c code is	universal."	Explain	this st	atement.

5. What might happen if codons encoded more than one amino acid?

Lesson 7.2: Multiple Choice

11	. The cell does not have the capability	y to repair damaged DNA.	
12	2. Point mutations can be described as s	s silent, missense, senseless, or nonsense.	
13	. A translocation mutation swaps section	tions from two non-homologous chromosomes.	
14	. Natural sunlight can cause mutations	ıs.	
15	5. Mutations are the source of all new g	genetic material in a species.	
Lesso	n 7.3: Critical Reading		
Name	Class	Date	
Read the	se passages from the text and answer th	the questions that follow.	

Beneficial Mutations

Some mutations have a positive effect on the organism in which they occur. They are called beneficial mutations. They lead to new versions of proteins that help organisms adapt to changes in their environment. Beneficial mutations are essential for evolution to occur. They increase an organism's changes of surviving or reproducing, so they are likely to become more common over time. There are several well-known examples of beneficial mutations. Here are just two:

a. Mutations in many bacteria that allow them to survive in the presence of antibiotic drugs. The mutations lead to antibiotic-resistant strains of bacteria.

b. A unique mutation is found in people in a small town in Italy. The mutation protects them from developing atherosclerosis, which is the dangerous buildup of fatty materials in blood vessels. The individual in which the mutation first appeared has even been identified.

Harmful Mutations

Imagine making a random change in a complicated machine such as a car engine. The chance that the random change would improve the functioning of the car is very small. The change is far more likely to result in a car that does not run well or perhaps does not run at all. By the same token, any random change in a gene's DNA is likely to result in a protein that does not function normally or may not function at all. Such mutations are likely to be harmful. Harmful mutations may cause genetic disorders or cancer.

- A **genetic disorder** is a disease caused by a mutation in one or a few genes. A human example is cystic fibrosis. A mutation in a single gene causes the body to produce thick, sticky mucus that clogs the lungs and blocks ducts in digestive organs.
- Cancer is a disease in which cells grow out of control and form abnormal masses of cells. It is generally caused by mutations in genes that regulate the cell cycle. Because of the mutations, cells with damaged DNA are allowed to divide without limits. Cancer genes can be inherited.

are allowed to divide without limits. Cancer genes can be inherited.
Questions
1. What is a beneficial mutation?
2. What is a harmful mutation?
3. What type of mutation can cause cancer?

7.3. Mutation www.ck12.org

Eukaryotic Gene Regulation

Read these passages from the text and answer the questions that follow.

In eukaryotic cells, the start of transcription is one of the most complicated parts of gene regulation. There may be many regulatory proteins and regulatory elements involved. Regulation may also involve enhancers. Enhancers are distant regions of DNA that can loop back to interact with a gene's promoter.

The TATA Box

Different types of cells have unique patterns of regulatory elements that result in only the necessary genes being transcribed. That's why a skin cell and nerve cell, for example, are so different from each other. However, some

patterns of regulatory elements are common to all genes, regardless of the cells in which they occur. An example is the **TATA box**. This is a regulatory element that is part of the promoter of most eukaryotic genes. A number of regulatory proteins bind to the TATA box, forming a multi-protein complex. It is only when all of the appropriate proteins are bound to the TATA box that RNA polymerase recognizes the complex and binds to the promoter. Once RNA polymerase binds, transcription begins.

Regulation During Development

The regulation of gene expression is extremely important during the development of an organism. Regulatory proteins must turn on certain genes in particular cells at just the right time so the organism develops normal organs and organ systems. **Homeobox genes** are an example of genes that regulate development. They code for regulatory proteins that switch on whole series of major developmental genes. In insects, homeobox genes called hox genes ensure that body parts such as limbs develop in the correct place.

Circle the letter of the correct choice.

- a. Using a gene to make a protein is called
 - a. protein expression.
 - b. gene expression.
 - c. gene regulation.
 - d. protein synthesis.
- b. Gene expression is regulated
 - a. to ensure that all cells make the same proteins.
 - b. to ensure that the correct proteins are made from the right genes.
 - c. to ensure that the correct proteins are made in the cells in which they are needed.
 - d. to ensure that all cells only use some genes.
- c. Which of the following statements concerning the lac operon is correct?
 - a. When lactose is present, the repressor protein binds to the operator.
 - b. When lactose is absent, a repressor protein binds to the operator.
 - c. When lactose is absent, a repressor protein binds to the promoter.
 - d. When lactose is present, the repressor protein binds to the promoter.
- d. Gene regulation during development involves
 - a. homeobox genes.
 - b. proto-oncogenes and tumor-suppressor genes.
 - c. the lac operon.
 - d. all of the above

- e. Which three factors are involved in eukaryotic gene regulation?
 - a. regulatory proteins, regulatory elements, and activators
 - b. regulatory proteins, operator, and promoter
 - c. regulatory proteins, regulatory elements, and RNA polymerase
 - d. regulatory proteins, regulatory elements, and enhancers
- f. Which of the following statements is correct? (1) Activators promote transcription by enhancing the interaction of RNA polymerase with the promoter. (2) Repressors promote transcription by enhancing the progress of RNA polymerase along the DNA strand. (3) Repressors prevent transcription by impeding the progress of RNA polymerase along the DNA strand. (4) Activators prevent transcription by impeding the interaction of RNA polymerase with the promoter.
 - a. 1 and 3
 - b. 2 and 4
 - c. 1 only
 - d. All 4 statements are correct.
- g. Which statement best describes the TATA box?
 - a. The TATA box is a regulatory element that is part of the promoter of most prokaryotic genes.
 - b. The TATA box is a regulatory element that is part of the promoter of most eukaryotic genes.
 - c. The TATA box is a regulatory protein that binds to the promoter of most eukaryotic genes.
 - d. The TATA box is a regulatory protein that binds to the promoter of most prokaryotic genes.
- h. Which of the following statements is correct?
 - a. Regulatory proteins bind to regulatory elements, which are located near promoters.
 - b. Regulatory elements bind to regulatory proteins, which are located near promoters.
 - c. Regulatory proteins bind to regulatory elements, which are also known as operons.
 - d. Regulatory proteins bind to regulatory elements, which are located near enahncers.

Lesson 8.1: Critica	I Reading	
Name	Class	Date

Chromosomes and Genes

Each species has a characteristic number of chromosomes. The human species is characterized by 23 pairs of chromosomes, as shown in the FlexBook.

Autosomes

Of the 23 pairs of human chromosomes, 22 pairs are autosomes. **Autosomes** are chromosomes that contain genes for characteristics that are unrelated to sex. These chromosomes are the same in males and females. The great majority of human genes are located on autosomes.

Sex Chromosomes

The remaining pair of human chromosomes consists of the **sex chromosomes**, X and Y. Females have two X chromosomes, and males have one X and one Y chromosome. In females, one of the X chromosomes in each cell is inactivated and known as a Barr body. This ensures that females, like males, have only one functioning copy of the X chromosome in each cell.

The X chromosome is much larger than the Y chromosome. The X chromosome has about 2,000 genes, whereas the Y chromosome has fewer than 100, none of which are essential to survival. Virtually all of the X chromosome genes are unrelated to sex. Only the Y chromosome contains genes that determine sex. A single Y chromosome gene, called SRY (which stands for sex-determining region Y gene), triggers an embryo to develop into a male. Without a Y chromosome, an individual develops into a female, so you can think of female as the default sex of the human species. Can you think of a reason why the Y chromosome is so much smaller than the X chromosome?

Human Genes

Humans have an estimated 20,000 to 22,000 genes. This may sound like a lot, but it really isn't. Far simpler species have almost as many genes as humans. However, human cells use splicing and other processes to make multiple proteins from the instructions encoded in a single gene. Of the 3 billion base pairs in the human genome, only about 25 percent make up genes and their regulatory elements. The functions of many of the other base pairs are still unclear.

The majority of human genes have two or more possible alleles. Differences in alleles account for the considerable genetic variation among people. In fact, most human genetic variation is the result of differences in individual DNA bases within alleles.

Questions

1. What are autosomes? How many do humans have?

2. Compare the X and Y chromosome.

3. In terms of sex chromosomes, what is the genotype of a female? a male?

Lesson 8.2: C	ritical Reading		
Name	Class	Date	

Genetic Disorders

Many genetic disorders are caused by mutations in one or a few genes. Other genetic disorders are caused by abnormal numbers of chromosomes.

Genetic Disorders Caused by Mutations

Table 8.1 lists several genetic disorders caused by mutations. Some of the disorders are caused by mutations in autosomal genes, others by mutations in X-linked genes. Which disorder would you expect to be more common in males than females?

8.2. Human Inheritance www.ck12.org

TABLE 8.1: Genetic Disorders Caused by Mutations

Genetic Disorder	Direct Effect of Mutation	Signs and Symptoms of the Disorder	Mode of Inheritance
Marfan syndrome	defective protein in con- nective tissue	heart and bone defects and unusually long, slen- der limbs and fingers	autosomal dominant
Sickle cell anemia	abnormal hemoglobin protein in red blood cells	· ·	autosomal recessive
Vitamin D-resistant rick- ets	lack of a substance needed for bones to absorb minerals	soft bones that easily be- come deformed, leading to bowed legs and other skeletal deformities	X-linked dominant
Hemophilia A	reduced activity of a pro- tein needed for blood clot- ting	internal and external bleeding that occurs easily and is difficult to control	X-linked recessive

Few genetic disorders are controlled by dominant alleles. A mutant dominant allele is expressed in every individual who inherits even one copy of it. If it causes a serious disorder, affected people may die young and fail to reproduce. Therefore, the mutant dominant allele is likely to die out of the population. A mutant recessive allele, such as the allele that causes sickle cell anemia, is not expressed in people who inherit just one copy of it. These people are called carriers. They do not have the disorder themselves, but they carry the mutant allele and can pass it to their offspring. Thus, the allele is likely to pass on to the next generation rather than die out.

Chromosomal Disorders

Mistakes may occur during meiosis that result in **nondisjunction**. This is the failure of replicated chromosomes to separate during meiosis II. Some of the resulting gametes will be missing a chromosome, while others will have an extra copy of the chromosome. If such gametes are fertilized and form zygotes, they usually do not survive. If they do survive, the individuals are likely to have serious genetic disorders. **Table** 8.2 lists several genetic disorders that are caused by abnormal numbers of chromosomes.

TABLE 8.2: Genetic Disorders Caused by Abnormal Numbers of Chromosomes

Genetic Disorder	Genotype	Phenotypic Effects	
Down syndrome	extra copy (complete or partial) of chromosome 21	developmental delays, distinctive facial appearance, and other abnor- malities	
Turner's syndrome	one X chromosome but no other sex chromosome (XO)	female with short height and infer- tility (inability to reproduce)	
Triple X syndrome	three X chromosomes (XXX)	female with mild developmental de- lays and menstrual irregularities	
Klinefelter's syndrome	one Y chromosome and two or more X chromosomes (XXY, XXXY)	male with problems in sexual development and reduced levels of the male hormone testosterone	

Having the wrong number of chromosomes causes the genetic disorders described in **Table** 8.2. Most chromosomal disorders involve the X chromosome. Look back at the X and Y chromosomes and you will see why. The X and Y chromosomes are very different in size, so nondisjunction of the sex chromosomes occurs relatively often.

Questions

1. What two main ways cause genetic disorders?

2. What are the signs and symptoms of sickle cell anemia?

3. Why are few genetic disorders controlled by dominant alleles?

4. Explain what causes chromosomal disorders.

5. Describe the cause and symptoms of Down syndrome.

Gene Cloning

Gene cloning is the process of isolating and making copies of a gene. This is useful for many purposes. For example, gene cloning might be used to isolate and make copies of a normal gene for gene therapy. Gene cloning involves four steps: isolation, ligation, transformation, and selection.

Read these passages from the text and answer the questions that follow.

- a. In isolation, an enzyme is used to break DNA at a specific base sequence. This is done to isolate a gene.
- b. During ligation, the enzyme DNA ligase combines the isolated gene with plasmid DNA from bacteria. (Plasmid DNA is circular DNA that is not part of a chromosome and can replicate independently.) The DNA that results is called **recombinant DNA**.
- c. In transformation, the recombinant DNA is inserted into a living cell, usually a bacterial cell. Changing an organism in this way is also called **genetic engineering**.

8.3. Biotechnology www.ck12.org

d. Selection involves growing transformed bacteria to make sure they have the recombinant DNA. This is a necessary step because transformation is not always successful. Only bacteria that contain the recombinant DNA are selected for further use.

Polymerase Chain Reaction

The **polymerase chain reaction** (**PCR**) makes many copies of a gene or other DNA segment. This might be done in order to make large quantities of a gene for genetic testing. PCR involves three steps: denaturing, annealing, and extension. They are repeated many times in a cycle to make large quantities of the gene.

- a. Denaturing involves heating DNA to break the bonds holding together the two DNA strands. This yields two single strands of DNA.
- b. Annealing involves cooling the single strands of DNA and mixing them with short DNA segments called primers. Primers have base sequences that are complementary to segments of the single DNA strands. As a result, bonds form between the DNA strands and primers.
- c. Extension occurs when an enzyme (Taq polymerase or Taq DNA polymerase) adds nucleotides to the primers. This produces new DNA molecules, each incorporating one of the original DNA strands.

1	3. The solar system evolved from stardust.
1	4. Species with few differences in their DNA sequences are closely related.
1	5. In order for fossils to provide useful information, they must be dated.
Lesso	on 9.1: Critical Reading
Name_	Class Date
Read th	ese passages from the text and answer the questions that follow.

The First Cells

How organic molecules such as RNA developed into cells is not known for certain. Scientists speculate that lipid membranes grew around the organic molecules. The membranes prevented the molecules from reacting with other molecules, so they did not form new compounds. In this way, the organic molecules persisted, and the first cells may have formed.

LUCA

No doubt there were many early cells of this type. However, scientists think that only one early cell (or group of

cells) eventually gave rise to all subsequent life on Earth. That one cell is called the **Last Universal Common Ancestor** (**LUCA**). It probably existed around 3.5 billion years ago. LUCA was one of the earliest prokaryotic cells. It would have lacked a nucleus and other membrane-bound organelles.

Photosynthesis and Cellular Respiration

The earliest cells were probably heterotrophs. Most likely they got their energy from other molecules in the organic "soup." However, by about 3 billion years ago, a new way of obtaining energy evolved. This new way was photosynthesis. Through photosynthesis, organisms could use sunlight to make food from carbon dioxide and water. These organisms were the first autotrophs. They provided food for themselves and for other organisms that began to consume them. After photosynthesis evolved, oxygen started to accumulate in the atmosphere. This has been dubbed the "oxygen catastrophe." Why? Oxygen was toxic to most early cells because they had evolved in its absence. As a result, many of them died out. The few that survived evolved a new way to take advantage of the oxygen. This second major innovation was cellular respiration. It allowed cells to use oxygen to obtain more energy from organic molecules.

Name	Class	Date

Circle the letter of the correct choice.

- a. Place the following in the order in which they evolved: eukaryotic cell, prokaryotic cell, photosynthesis, organic molecules.
 - a. eukaryotic cell prokaryotic cell photosynthesis organic molecules
 - b. prokaryotic cell eukaryotic cell photosynthesis organic molecules
 - c. organic molecules prokaryotic cell photosynthesis eukaryotic cell
 - d. organic molecules photosynthesis prokaryotic cell eukaryotic cell
- b. Which of the following statements is true concerning LUCA? (1) LUCA was a cell. (2) All life on Earth evolved from LUCA. (3) LUCA probably existed probably around 4.5 billion years ago.
 - a. 1 only
 - b. 2 and 2
 - c. 1 and 2
 - d. 1, 2, and 3
- c. The RNA world hypothesis states that
 - a. early life was based on RNA as the first organic molecule.
 - b. RNA evolved soon after the formation of the world.
 - c. the first cells were made of RNA and lipids.
 - d. all of the above
- d. The "soup" of molecules refers to
 - a. an ocean full of a mixture of many different substances.
 - b. organic molecules created from inorganic chemicals in Earth's early atmosphere.

- c. a Earth full of volcanic eruptions, thunder, and lightning.
- d. the classic evolution experiments of Campbell and Chunky.
- e. Early Earth
 - a. had a primitive atmosphere of ammonia, methane, water vapor, and carbon dioxide.
 - b. lacked much oxygen gas.
 - c. probably had a very hot environment.
 - d. all of the above
- f. Which of the following can be considered fossils?
 - a. a 1 billion year-old rock.
 - b. a 1 billion year-old piece of amber.
 - c. a 1 billion year-old piece of amber with a primitive insect inside.
 - d. all of the above
- g. "We are made of stardust" refers to
 - a. the dust of dead skin cells we shed every day.
 - b. the rotating cloud of stardust that formed the planets.
 - c. the gases in the stars that formed the gases in the atmosphere.
 - d. the rotating cloud of stardust that formed LUCA and all the organisms that evolved later.
- h. Place the mouse, fruit fly, duck, and gorilla in order of their relatedness to humans, from least related to most related.
 - a. mouse fruit fly duck gorilla
 - b. fruit fly mouse duck gorilla
 - c. gorilla mouse duck fruit fly

Name	Class	Date						
Read these passa	ges from the text and answer	the questions that follow.						

Setting the Stage: The Late Precambrian

The late Precambrian is the time from about 2 billion to half a billion years ago. During this long span of time, Earth experienced many dramatic geologic and climatic changes.

- Continents drifted. They collided to form a gigantic supercontinent and then broke up again and moved apart. Continental drift changed climates worldwide and caused intense volcanic activity.
- Carbon dioxide levels in the atmosphere rose and fell. This was due to volcanic activity and other factors. When the levels were high, they created a greenhouse effect. More heat was trapped on Earth's surface, and the climate became warmer. When the levels were low, less heat was trapped and the planet cooled. Several

times, cooling was severe enough to plunge Earth into an ice age. One ice age was so cold that snow and ice completely covered the planet.

Life During the Late Precambrian

The dramatic changes of the late Precambrian had a major impact on Earth's life forms. Living things that could not adapt died out. They were replaced by organisms that evolved new adaptations. These adaptations included sexual reproduction, specialization of cells, and multicellularity.

- Sexual reproduction created much more variety among offspring. This increased the chances that at least some
 of them would survive when the environment changed. It also increased the speed at which evolution could
 occur.
- Some cells started to live together in colonies. In some colonies, cells started to specialize in doing different jobs. This made the cells more efficient as a colony than as individual cells.
- By 1 billion years ago, the first multicellular organisms had evolved. They may have developed from colonies
 of specialized cells. Their cells were so specialized they could no longer survive independently. However,
 together they were mighty. They formed an organism that was bigger, more efficient, and able to do much
 more than any single-celled organism ever could.

The Precambrian Extinction

At the close of the Precambrian 544 million years ago, a mass extinction occurred. In a **mass extinction**, many or even most species abruptly disappear from Earth. There have been five mass extinctions in Earth's history. Many scientists think we are currently going through a sixth mass extinction. What caused the Precambrian mass extinction? A combination of climatic and geologic events was probably responsible. No matter what the cause, the extinction paved the way for a burst of new life during the following Paleozoic Era.

Less	on 9.3: Critical Reading
Name_	Class Date

Linnaean Classification

Read these passages from the text and answer the questions that follow.

All modern classification systems have their roots in the **Linnaean classification system.** It was developed by Swedish botanist Carolus Linnaeus in the 1700s. He tried to classify all living things that were known at his time. He grouped together organisms that shared obvious physical traits, such as number of legs or shape of leaves. For his contribution, Linnaeus is known as the "father of taxonomy." The Linnaean system of classification consists of a hierarchy of groupings, called **taxa** (singular, taxon). Taxa range from the kingdom to the species. The **kingdom** is the largest and most inclusive grouping. It consists of organisms that share just a few basic similarities. Examples

are the plant and animal kingdoms. The **species** is the smallest and most exclusive grouping. It consists of organisms that are similar enough to produce fertile offspring together. Closely related species are grouped together in a **genus**.

Binomial Nomenclature

Perhaps the single greatest contribution Linnaeus made to science was his method of naming species. This method, called **binomial nomenclature**, gives each species a unique, two-word Latin name consisting of the genus name and the species name. An example is *Homo sapiens*, the two-word Latin name for humans. It literally means "wise human." This is a reference to our big brains. Why is having two names so important? It is similar to people having a first and a last name. You may know several people with the first name Michael, but adding Michael's last name usually pins down exactly whom you mean. In the same way, having two names uniquely identifies a species.

Revisions in Linnaean Classification

Linnaeus published his classification system in the 1700s. Since then, many new species have been discovered. The biochemistry of organisms has also become known. Eventually, scientists realized that Linnaeus's system of classification needed revision. A major change to the Linnaean system was the addition of a new taxon called the domain. A **domain** is a taxon that is larger and more inclusive than the kingdom. Most biologists agree there are three domains of life on Earth: Bacteria, Archaea, and Eukaryota. Both Bacteria and Archaea consist of single-celled prokaryotes. Eukaryota consists of all eukaryotes, from single-celled protists to humans. This domain includes the Animalia (animals), Plantae (plants), Fungi (fungi), and Protista (protists) kingdoms.

Lesson 10.1: Cr	itical Reading	
Name	Class	Date

The Voyage of the Beagle

In 1831, when Darwin was just 22 years old, he set sail on a scientific expedition on a ship called the *HMS Beagle*. He was the naturalist on the voyage. As a naturalist, it was his job to observe and collect specimens of plants, animals, rocks, and fossils wherever the expedition went ashore.

Darwin was fascinated by nature, so he loved his job on the *Beagle*. He spent more than 3 years of the 5-year trip exploring nature on distant continents and islands. While he was away, a former teacher published Darwin's accounts of his observations. By the time Darwin finally returned to England, he had become famous as a naturalist.

Darwin's Observations

During the long voyage, Darwin made many observations that helped him form his theory of evolution. For example:

- He visited tropical rainforests and other new habitats where he saw many plants and animals he had never seen before. This impressed him with the great diversity of life.
- He experienced an earthquake that lifted the ocean floor 2.7 meters (9 feet) above sea level. He also found rocks containing fossil sea shells in mountains high above sea level. These observations suggested that continents and oceans had changed dramatically over time and continue to change in dramatic ways.
- He visited rock ledges that had clearly once been beaches that had gradually built up over time. This suggested that slow, steady processes also change Earth's surface.
- He dug up fossils of gigantic extinct mammals, such as the ground sloth. This was hard evidence that organisms looked very different in the past. It suggested that living things like Earth's surface change over time.

The Galápagos Islands

Darwin's most important observations were made on the **Galápagos Islands**. This is a group of 16 small volcanic islands 966 kilometers (600 miles) off the west coast of South America.

Individual Galápagos Islands differ from one another in important ways. Some are rocky and dry. Others have better soil and more rainfall. Darwin noticed that the plants and animals on the different islands also differed. For example, the giant tortoises on one island had saddle-shaped shells, while those on another island had dome-shaped shells. People who lived on the islands could even tell the island a turtle came from by its shell. This started Darwin thinking about the origin of species. He wondered how each island came to have its own type of tortoise.

Evidence from Biogeography

Biogeography is the study of how and why plants and animals live where they do. It provides more evidence for evolution. Let's consider the camel family as an example.

Biogeography of Camels: An Example

Today, the camel family includes different types of camels. All of today's camels are descended from the same camel ancestors. These ancestors lived in North America about a million years ago.

Early North American camels migrated to other places. Some went to East Asia. They crossed a land bridge during the last ice age. A few of them made it all the way to Africa. Others went to South America. They crossed the Isthmus of Panama. Once camels reached these different places, they evolved independently. They evolved adaptations that suited them for the particular environment where they lived. Through natural selection, descendants of the original camel ancestors evolved the diversity they have today.

Island Biogeography

The biogeography of islands yields some of the best evidence for evolution. Consider the birds called finches that Darwin studied on the Galápagos Islands. All of the finches probably descended from one bird that arrived on the islands from South America. Until the first bird arrived, there had never been birds on the islands. The first bird was a seed eater. It evolved into many finch species. Each species was adapted for a different type of food. This is an example of **adaptive radiation**. This is the process by which a single species evolves into many new species to fill available niches.

Eyewitness to Evolution

In the 1970s, biologists Peter and Rosemary Grant went to the Galápagos Islands. They wanted to re-study Darwin's finches. They spent more than 30 years on the project. Their efforts paid off. They were able to observe evolution by natural selection actually taking place. While the Grants were on the Galápagos, a drought occurred. As a result, fewer seeds were available for finches to eat. Birds with smaller beaks could crack open and eat only the smaller seeds. Birds with bigger beaks could crack and eat seeds of all sizes. As a result, many of the small-beaked birds died in the drought. Birds with bigger beaks survived and reproduced. Within 2 years, the average beak size in the finch population increased. Evolution by natural selection had occurred.

Name	Class	Date

Forces of Evolution

The conditions for Hardy-Weinberg equilibrium are unlikely to be met in real populations. The Hardy-Weinberg theorem also describes populations in which allele frequencies are not changing. By definition, such populations are not evolving. How does the theorem help us understand evolution in the real world?

From the theorem, we can infer factors that cause allele frequencies to change. These factors are the forces of evolution. There are four such forces: mutation, gene flow, genetic drift, and natural selection.

Mutation

Mutation creates new genetic variation in a gene pool. It is how all new alleles first arise. In sexually reproducing species, the mutations that matter for evolution are those that occur in gametes. Only these mutations can be passed to offspring. For any given gene, the chance of a mutation occurring in a given gamete is very low. Thus, mutations alone do not have much effect on allele frequencies. However, mutations provide the genetic variation needed for other forces of evolution to act.

Gene Flow

Gene flow occurs when people move into or out of a population. If the rate of migration is high, this can have a significant effect on allele frequencies. Both the population they leave and the population they enter may change.

During the Vietnam War in the 1960s and 1970s, many American servicemen had children with Vietnamese women. Most of the servicemen returned to the United States after the war. However, they left copies of their genes behind in their offspring. In this way, they changed the allele frequencies in the Vietnamese gene pool. Was the gene pool of the American population also affected? Why or why not?

Genetic Drift

Genetic drift is a random change in allele frequencies that occurs in a small population. When a small number of parents produce just a few offspring, allele frequencies in the offspring may differ, by chance, from allele frequencies in the parents. This is like tossing a coin. If you toss a coin just a few times, you may by chance get more or less than the expected 50 percent heads or tails. In a small population, you may also by chance get different allele frequencies than expected in the next generation. In this way, allele frequencies may drift over time. Genetic drift occurs under two special conditions. They are called bottleneck effect and founder effect.

- a. Bottleneck effect occurs when a population suddenly gets much smaller. This might happen because of a natural disaster, such as a forest fire. By chance, allele frequencies of the survivors may be different from those of the original population.
- b. Founder effect occurs when a few individuals start, or found, a new population. By chance, allele frequencies of the founders may be different from allele frequencies of the population they left.

Questions

1. What are the forces of evolution?

2. Describe the type of mutations that affect evolution. Why?

	esson 10.3: Multiple Choice ame Class Date
5.	Describe one special condition under which genetic drift occurs.
4.	What is genetic drift?
3.	Was the gene pool of the American population also affected by the gene flow described above? Why or why not?

Circle the letter of the correct choice.

- a. The main difference between macroevolution and microevolution is
 - a. the time frame of the evolutionary process.
 - b. the species that evolve during each.
 - c. that microevolution is only for small organisms, and macroevolution is for large organisms.
 - d. all of the above
- b. Which of the following statements is correct?
 - a. Individuals do not evolve, genes do evolve.
 - b. Individuals do not evolve, populations do evolve.
 - c. Populations do not evolve, individuals do evolve.

- d. Populations do not evolve, species do evolve.
- c. Which of the following statements is true concerning mutations? (1) Mutations are how all new alleles first arise. (2) Mutations create new genetic variation in a gene pool. (3) Only mutations that occur in gametes influence evolution. (4) Mutations really do not have much influence on allele frequencies.
 - a. 1 and 2
 - b. 2 and 4
 - c. 1, 2, and 3
 - d. 1, 2, 3, and 4
- d. In a population with 100 members, the total number of copies of each gene in the population is
 - a. 50.
 - b. 100.
 - c. 200.
 - d. 400.

Introduction

Macroevolution is evolution over geologic time above the level of the species. One of the main topics in macroevolution is how new species arise. The process by which a new species evolves is called **speciation**. How does speciation occur? How does one species evolve into two or more new species?

Origin of Species

To understand how a new species forms, it's important to review what a species is. A species is a group of organisms that can breed and produce fertile offspring together in nature. For a new species to arise, some members of a species

must become reproductively isolated from the rest of the species. This means they can no longer interbreed with other members of the species. How does this happen? Usually they become geographically isolated first.

Allopatric Speciation

Assume that some members of a species become geographically separated from the rest of the species. If they remain separated long enough, they may evolve genetic differences. If the differences prevent them from interbreeding with members of the original species, they have evolved into a new species. Speciation that occurs in this way is called **allopatric speciation**.

Sympatric Speciation

Less often, a new species arises without geographic separation. This is called **sympatric speciation**. The following example shows one way this can occur.

- a. Hawthorn flies lay eggs in hawthorn trees. The eggs hatch into larvae that feed on hawthorn fruits. Both the flies and trees are native to the U.S.
- b. Apple trees were introduced to the U.S. and often grow near hawthorn trees. Some hawthorn flies started to lay eggs in nearby apple trees. When the eggs hatched, the larvae fed on apples.
- c. Over time, the two fly populations those that fed on hawthorn trees and those that preferred apple trees evolved reproductive isolation. Now they are reproductively isolated because they breed at different times. Their breeding season matches the season when the apple or hawthorn fruits mature.
- d. Because they rarely interbreed, the two populations of flies are evolving other genetic differences. They appear to be in the process of becoming separate species.

Circle the letter of the correct choice.

- a. Which statement best describes allopatric speciation?
 - a. Speciation that occurs without reproductive separation.
 - b. Speciation that occurs without geographic separation.
 - c. Speciation that occurs when some members of a species become geographically separated from the rest of the species.
 - d. Speciation that occurs when some members of a species become reproductively separated from the rest of the species.
- b. Which statement best describes sympatric speciation?
 - a. Speciation that occurs without reproductive separation.
 - b. Speciation that occurs without geographic separation.

- c. Speciation that occurs when some members of a species become geographically separated from the rest of the species.
- d. Speciation that occurs when some members of a species become reproductively separated from the rest of the species.
- c. Which is the best definition of a "species"?
 - a. A group of organisms that can breed and produce fertile offspring together.
 - b. A group of organisms that can breed and produce infertile offspring together.
 - c. A group of organisms that can breed together.
 - d. A group of organisms that look and act similar.
- d. An example of coevolution would be
 - a. the evolution of wings in bats and birds.
 - b. the toad and the flies they eat.
 - c. the hummingbird and the tubular flower it pollinates.
 - d. all of the above
- e. Which statement is true concerning gradualism? (1) Gradualism occurs when geologic and climatic conditions are stable. (2) Darwin thought evolution occurred this way. (3) This type of evolution may result in long periods of little change.
 - a. 1 only
 - b. 1 and 2
 - c. 1 and 3
 - d. 1, 2, and 3
- f. Punctuated equilibrium is
 - a. well supported by the fossil record.
 - b. a slow form of evolution.
 - c. how Darwin proposed evolution occurs.
 - d. none of the above
- g. The hawthorn fly
 - a. is undergoing allopatric speciation.
 - b. can live on either hawthorn trees or apple trees.
 - c. has been geographically separated by the planting of new tree species.
 - d. all of the above
- h. The Kaibab squirrel
 - a. is undergoing allopatric speciation.
 - b. is undergoing sympatric speciation.
 - c. were geographically separated from Abert's squirrels by the formation of the Grand Canyon.
 - d. both a and c

11.1 The Science of Ecology

Lesson	11.1: True or False
Name	Class Date
Write true	if the statement is true or false if the statement is false.
1. B	Biotic factors include sunlight, soil, temperature, and water.
2. L	Like nutrients and water, energy also recycles through an ecosystem.
3. A	An ecosystem consists of all the biotic and abiotic factors in an area and their interactions.
4. H	Herbivores are a necessary link between producers and other consumers.
5. A	A niche refers to the place an organism lives within its ecosystem.
6. Г	Dung beetles eat animal feces.
7. A	Autotrophs make their own food.
8. C	Organisms use 90% of the available energy at each trophic level.
9. C	Carnivores include lions, polar bears, hawks, frogs, salmon, and deer.
10.	Biomass increases at the upper levels of a food chain.
11.	Producers occupy the first trophic level.
12.	Scavengers include vultures and raccoons.
13.	In a complex ecosystem, it is likely that two different species will occupy the same niche.
14.	The habitat is the role of a species in its ecosystem.
15.	A food web shows how energy flows through an ecosystem.
Lesson	11.1: Critical Reading
Name	Class Date
Read these	e passages from the text and answer the questions that follow.
Trophic L	avalc

Trophic Levels

The feeding positions in a food chain or web are called **trophic levels**. The different trophic levels are defined in **Table 11.1**. All food chains and webs have at least two or three trophic levels. Generally, there are a maximum of four trophic levels. Examples are also given in the table.

TABLE 11.1: Trophic Levels

Trophic LevelWhere It Gets FoodExample1st Trophic Level: ProducerMakes its own foodPlants make food

TABLE 11.1: (continued)

Trophic Level Where It Gets Food Example

2nd Trophic Level: Primary Con- Consumes producers Mice eat plant seeds

sumer

3rd Trophic Level: Secondary Con- Consumes primary consumers Snakes eat mice

sumer

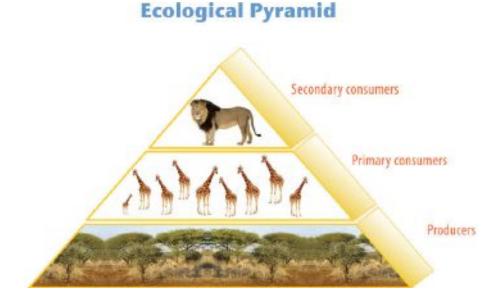

4th Trophic Level: Tertiary Con- Consumes secondary consumers Hawks eat snakes

sumer

Many consumers feed at more than one trophic level. Humans, for example, are primary consumers when they eat plants such as vegetables. They are secondary consumers when they eat cows. They are tertiary consumers when they eat salmon.

Trophic Levels and Energy

Energy is passed up a food chain or web from lower to higher trophic levels. However, only about 10 percent of the energy at one level is available to the next level. This is represented by the pyramid below. What happens to the other 90 percent of energy? It is used for metabolic processes or given off to the environment as heat. This loss of energy explains why there are rarely more than four trophic levels in a food chain or web. Sometimes there may be a fifth trophic level, but usually there's not enough energy left to support any additional levels.

Ecological Pyramid. This pyramid shows how energy and biomass decrease from lower to higher trophic levels. Assume that producers in this pyramid have 1,000,000 kilocalories of energy. How much energy is available to primary consumers? (*Images of lion and landscape copyright by Eric Isselée*, 2010, and image of giraffe copyright Kletr, 2010. Used under licenses from Shutterstock.com. Compilation created by CK-12 Foundation.)

Trophic Levels and Biomass

With less energy at higher trophic levels, there are usually fewer organisms as well. Organisms tend to be larger in size at higher trophic levels, but their smaller numbers result in less biomass. **Biomass** is the total mass of organisms at a trophic level. The decrease in biomass from lower to higher levels is also represented by the figure above.

Questions

1. What is a trophic level?

2. Which trophic level includes humans?

3. What types of organisms are in the first trophic level? Give an example.

4. Assume that producers in an ecosystem have 1,000,000 kilocalories of energy. How much energy is available to primary consumers?

5. Which trophic level has the greatest biomass?

Lesson	11.1	: Multi	ple C	hoice

Name	Class	Date
------	-------	------

Circle the letter of the correct choice.

- a. Examples of biotic factors include
 - a. grass, flowers, and sunlight
 - b. grass, trees, bees, and ants.
 - c. grass, trees, soil, and water.
 - d. all of the above
- b. Components of an ecosystem include
 - a. soil, sunlight, water, and weather.
 - b. grass, trees, bees, and ants.
 - c. all the biotic and abiotic factors in an area.
 - d. all of the above.
- c. Which describes the possible flow of energy in an ecosystem?
 - a. snakes to frogs to caterpillars to trees
 - b. trees to frogs to snakes to caterpillars
 - c. trees to caterpillars to frogs to snakes
 - d. caterpillars to trees to frogs to snakes
- d. The relationship between autotrophs and producers is
 - a. that autotrophs make the food the producers eat.
 - b. that producers make the food the autotrophs eat.
 - c. that autotrophs eat producers.
 - d. that they are the same organisms.
- e. Which statement best describes a trophic level?
 - a. A trophic level is the feeding position of an organism in a food chain or web.
 - b. A trophic level is the position of an organism in an ecosystem.
 - c. A trophic level is the niche of an organism in an ecosystem.
 - d. A trophic level is the feeding role of an organism in an ecosystem.
- f. Examples of decomposers include
 - a. algae and cyanobacteria.
 - b. earthworms, dung beetles, and spiders.
 - c. vultures and raccoons.
 - d. all of the above.

- g. Which organism would usually be in the fourth trophic level?
 - a. rats
 - b. humans
 - c. rabbits
 - d. hawks
- h. Which statement best defines ecology?
 - a. The study of how living things interact with each other.
 - b. The study of how living things interact with each other and with their environment.
 - c. The study of how living things interact with their environment.
 - d. The study of how living things interact with their habitat.

11.2 Recycling Matter

Name	Class	Date	
Write true if the states	nent is true or false if th	ne statement is false.	
1. Just like ene	rgy, matter is lost as it p	passes through an ecosystem.	
2. Sublimation	occurs when water cha	nges to water vapor.	
3. Part of a cyc	ele that holds an elemen	t or water for a short period of time is a reserve	oir pool.
4. The deep oc	ean store carbon for the	usands of years or more.	
5. The ocean is	s a reservoir for water.		
6. Photosynthe	sis removes carbon diox	kide from the atmosphere.	
7. The water of	n Earth is billions of yea	ars old.	
8. Oxygen mal	xes up most of Earth's a	tmosphere.	
9. Transpiratio	n occurs when plants re	lease water vapor through their stomata.	
10. Nitrogen fi	xation is done by by nit	rogen-fixing plants.	
11. Cellular res	spiration releases oxyge	n into the atmosphere as carbon dioxide.	
12. Water drop	lets fall from the atmos	phere as condensation.	
13. The water	cycle takes place on, ab	ove, and below Earth's surface.	
14. Carbon cyc	eles quickly between org	ganisms and the atmosphere.	
15. Plants use	nitrogen gas from the ai	r to make organic compounds.	
Lesson 11.2: Cı	titical Reading		
Name	Class	Date	

Introduction

Where does the water that is needed by your cells come from? Or the carbon and nitrogen that is needed to make your organic molecules? Unlike energy, matter is not lost as it passes through an ecosystem. Instead, matter is recycled. This recycling involves specific interactions between the biotic and abiotic factors in an ecosystem.

Biogeochemical Cycles

The chemical elements and water that are needed by organisms continuously recycle in ecosystems. They pass through biotic and abiotic components of the biosphere. That's why their cycles are called **biogeochemical cycles**. For example, a chemical might move from organisms ("bio") to the atmosphere or ocean ("geo") and back to

organisms again. Elements or water may be held for various periods of time in different parts of a cycle.

- Part of a cycle that holds an element or water for a short period of time is called an **exchange pool**. For example, the atmosphere is an exchange pool for water. It usually holds water (in the form of water vapor) for just a few days.
- Part of a cycle that holds an element or water for a long period of time is called a **reservoir**. The ocean is a reservoir for water. The deep ocean may hold water for thousands of years.

Questions
1. Why is matter not lost as it passes through an ecosystem?
2. What is a biogeochemical cycle?
2. What is an analysis and 19. Circum annuals
3. What is an exchange pool? Give an example.
4. What is a reservoir? Give an example.

Circle the letter of the correct choice.

- a. Which statement best describes a biogeochemical cycle?
 - a. A cycle that recycles chemical elements and water.
 - b. A cycle that continuously cycles chemical elements and water.
 - c. A cycle that continuously cycles chemical elements and water that are needed by organisms.
 - d. A cycle that continuously cycles chemical elements and water that are needed by organisms through an ecosystem.
- b. An example of an exchange pool is
 - a. the atmosphere for water.
 - b. the ocean for water.
 - c. the Earth for carbon.
 - d. all of the above.
- c. The relationship between condensation and precipitation is that
 - a. precipitation needs to occur prior to condensation.
 - b. condensation needs to occur prior to precipitation.
 - c. both are parts of the water cycle.
 - d. both b and c describe the relationship.
- d. The best description of the relationship between runoff and groundwater is that
 - a. runoff turns into groundwater.
 - b. groundwater turns into runoff.
 - c. both result from precipitation and may end up in bodies of water.
 - d. none of the above
- e. Nitrogen fixation
 - a. is the process of changing nitrogen gas to nitrates.
 - b. is the process of changing nitrates to nitrogen gas.
 - c. is carried out by nitrogen-fixing plants.
 - d. naturally occurs in the atmosphere.
- f. In terms of carbon and the atmosphere, autotrophs
 - a. remove carbon through photosynthesis and release carbon by cellular respiration.
 - b. remove carbon through cellular respiration and release carbon by photosynthesis.
 - c. remove oxygen through photosynthesis but release carbon by cellular respiration.
 - d. only remove carbon through photosynthesis.
- g. Which statement is correct?
 - a. Nitrogen must cycle through an ecosystem because it is used to make proteins and nucleic acids.
 - b. Nitrogen makes up most of Earth's atmosphere.
 - c. Nitrogen gas from the atmosphere cannot be used by plants to make organic compounds.
 - d. all of the above
- h. Which statement is correct?
 - a. Fossil fuels can store carbon for millions of years, and release carbon when burned.
 - b. Fossil fuels can store carbon for millions of years, and release oxygen when burned.
 - c. Fossil fuels can store oxygen for millions of years, and release carbon when burned.

d. Fossil fuels can store nitrogen for millions of years, and release nitrogen when burned.

Write t	true if the statement is true or false if the statement is false.
	1. Biomes may be terrestrial, aquatic, or atmospheric.
	2. Temperature gets cooler as you move away from the equator.
	3. Terrestrial biomes include all the land and water areas on Earth where organisms live.
	4. Sunlight penetrates roughly 200 meters into the water.
	5. Climate is the average weather in an area over a long period of time.
	6. The growing season may last all year in a hot, wet climate.
	7. Temperature refers to the conditions of the atmosphere from day to day.
	8. Phytoplankton are tiny animals that feed on zooplankton.
	9. Climate determines plant growth.
	10. The terrifying anglerfish lives between 100 and 400 feet below sea level.
	11. Plankton are tiny aquatic organisms that swim around in the photic zone.
	12. The photic zone is water deeper than 200 meters.
	13. The boreal forest in central Alaska has low biodiversity.
	14. Aquatic biomes in the ocean are called marine biomes.
	15. When aquatic organisms die, they sink to the bottom, so water near the bottom may contain more nutrients ater at other depths.
Less	on 11.3: Critical Reading
Name_	Class Date

Terrestrial Biomes

Terrestrial biomes include all the land areas on Earth where organisms live. The distinguishing features of terrestrial biomes are determined mainly by climate. Terrestrial biomes include tundras, temperate forests and grasslands, chaparral, temperate and tropical deserts, and tropical forests and grasslands.

Terrestrial Biomes and Climate

Read these passages from the text and answer the questions that follow.

Climate is the average weather in an area over a long period of time. Weather refers to the conditions of the atmosphere from day to day. Climate is generally described in terms of temperature and moisture. Temperature

11.3. Biomes www.ck12.org

falls from the equator to the poles. Therefore, major temperature zones are based on latitude. They include tropical, temperate, and arctic zones (see figure below). However, other factors besides latitude may also influence temperature. For example, land near the ocean may have cooler summers and warmer winters than land farther inland. This is because water gains and loses heat more slowly than does land, and the water temperature influences the temperature on the coast. Temperature also falls from lower to higher altitudes. That's why tropical zone mountaintops may be capped with snow.

(Image courtesy of CK-12 Foundation and under the Creative Commons license CC-BY-NC-SA 3.0.)

In terms of moisture, climates can be classified as arid (dry), semi-arid, humid (wet), or semi-humid. The amount of moisture depends on both precipitation and evaporation. Precipitation increases moisture. Evaporation decreases moisture.

Climate and Plant Growth

Plants are the major producers in terrestrial biomes. They have five basic needs: air, warmth, sunlight, water, and nutrients. How well these needs are met in a given location depends on the growing season and soil quality, both of which are determined mainly by climate.

- The **growing season** is the period of time each year when it is warm and wet enough for plants to grow. The growing season may last all year in a hot, wet climate but just a few months in a cooler or drier climate.
- Plants grow best in soil that contains plenty of nutrients and organic matter. Both are added to soil when plant litter and dead organisms decompose. Decomposition occurs too slowly in cold climates and too quickly in hot, wet climates for nutrients and organic matter to accumulate. Temperate climates usually have the best soil for plant growth.

Questions

1. What is a terrestrial biome? Give two examples.

2. What is the difference between climate and weather?

3. How do precipitation and evaporation affect climate?

4. How does climate determine plant growth?

5. What do plants need to grow? How are these needs affected by climate?

11.3. Biomes www.ck12.org

- Lesson 12.4: The Biodiversity Crisis
- Lesson 12.5: Natural Resources and Climate Change

12.1 Community Interactions

1. All b2. Cam3. Preda	e statement is true or false if the statement is false. iomes, except a desert, have populations of interacting species. ouflage is an adaptation that has evolved through natural selection. ation is a relationship in which the prey consumes the predator.
2. Cam-	ouflage is an adaptation that has evolved through natural selection.
3. Preda	
	ntion is a relationship in which the prey consumes the predator.
4. Inter	
	specific competition occurs between members of the same species.
5. Inter	specific competition often leads to extinction, or it may lead to greater specialization.
6. A ke	ystone species is one that plays an especially important role in its population.
7. Rock	that hardens from lava is an example of primary succession.
8. Mutu	alism is a symbiotic relationship in which both species benefit.
9. The	first species to colonize a disturbed area such as this are called primary species.
10. If a	parasite kills its host, the parasite may also die.
11. Intr	aspecific competition leads to the evolution of better adaptations within a species.
12. Sec	ondary succession may occur after a forest fire.
13. A p	opulation consists of all the communities of all the species in the same area.
14. The	re are three major types of community interactions: predation, competition, and selection.
15. Lic	nens that can live on bare rock may be pioneer species after a flood.

Symbiotic Relationships

Symbiosis is a close relationship between two species in which at least one species benefits. For the other species, the relationship may be positive, negative, or neutral. There are three basic types of symbiosis: mutualism, commensalism, and parasitism.

Mutualism

Mutualism is a symbiotic relationship in which both species benefit. An example of mutualism involves goby fish and shrimp (see figure below). The nearly blind shrimp and the fish spend most of their time together. The shrimp maintains a burrow in the sand in which both the fish and shrimp live. When a predator comes near, the fish touches

the shrimp with its tail as a warning. Then, both fish and shrimp retreat to the burrow until the predator is gone. From their relationship, the shrimp gets a warning of approaching danger. The fish gets a safe retreat and a place to lay its eggs.

The multicolored shrimp in the front and the green goby fish behind it have a mutualistic relationship. (Image courtesy of Haplochromis and under the Creative Commons license CC-BY-SA 3.0.)

Commensalism

Commensalism is a symbiotic relationship in which one species benefits while the other species is not affected. One species typically uses the other for a purpose other than food. For example, mites attach themselves to larger flying insects to get a "free ride." Hermit crabs use the shells of dead snails for homes.

Parasitism

Parasitism is a symbiotic relationship in which one species (the **parasite**) benefits, while the other species (the **host**) is harmed. Many species of animals are parasites, at least during some stage of their life. Most species are also hosts to one or more parasites. Some parasites live on the surface of their host. Others live inside their host. They may enter the host through a break in the skin or in food or water. For example, roundworms are parasites of mammals, including humans, cats, and dogs. The worms produce huge numbers of eggs, which are passed in the host's feces to the environment. Other individuals may be infected by swallowing the eggs in contaminated food or water.

Some parasites kill their host, but most do not. It's easy to see why. If a parasite kills its host, the parasite is also likely to die. Instead, parasites usually cause relatively minor damage to their host.

Questions

1. What is symbiosis?

3. What is commensalism? Give an example.

4. What is parasitism? Give an example.

5. Why don't most parasites kill their host?

Lesson 12.1: Multiple Choice

Name_____ Class____ Date____

Circle the letter of the correct choice.

- a. Which of the following would NOT be a community?
 - a. All the plants, insects, and soil in your back yard.
 - b. All the many varieties of dogs in your neighborhood.
 - c. All the fish in an aquarium.
 - d. none of the above
- b. Community interactions include
 - a. predation.
 - b. competition.
 - c. symbiosis.
 - d. all of the above.
- c. Which is an example of a predator-prey relationship?
 - a. The relationship between a duck and a pond of water.
 - b. The relationship between a lion and a zebra.
 - c. The relationship between a bee and a flower.
 - d. The relationship between a hen and a rooster.
- d. The main difference among the types of symbiotic relationships is
 - a. how many species either benefit or are harmed.
 - b. how many species are eaten.
 - c. how many species are protected.
 - d. all of the above.
- e. An example of interspecific competition is
 - a. two male birds competing for the same female.
 - b. two male lions competing to lead the same pride.
 - c. two species of big cats competing for the same antelope.
 - d. all of the above.
- f. Which of the following is a parasite?
 - a. the goby fish
 - b. the hermit crab
 - c. the shrimp
 - d. the roundworm
- g. Which could possibly be a pioneer species during primary succession?
 - a. the first grass on new soil
 - b. the first lichen on new rock
 - c. the first layer of grass in a new park
 - d. the first trees to grow in a new forest
- h. Camouflage is
 - a. an adaptation that evolved through natural selection.
 - b. a necessary trait for commensalism.
 - c. part of a well-adapted pioneer species traits.
 - d. all of the above.

15. Specie below the carryin		nments are usually r -selected, and their population size is usually well
Lesson 12.2	: Critical Reading	
Name	Class	Date
Read these passa	iges from the text and answer	the questions that follow.

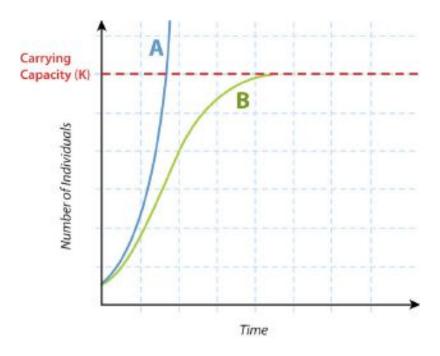

Patterns of Population Growth

Populations may show different patterns of growth. The growth pattern depends partly on the conditions under which a population lives.

Exponential Growth

Under ideal conditions, populations of most species can grow at exponential rates. Curve A in the graph below

represents **exponential growth**. The population starts out growing slowly. As population size increases, the growth rate also increases. The larger the population becomes, the faster it grows.

Exponential and Logistic Growth. Curve A shows exponential growth. Curve B shows logistic growth. (Image courtesy of CK-12 Foundation and under the Creative Commons license CC-BY-NC-SA 3.0.)

Logistic Growth

Most populations do not live under ideal conditions. Therefore, most do not grow exponentially. Certainly, no population can keep growing exponentially for very long. Many factors may limit growth. Often, the factors are density-dependent. These are factors that kick in when the population becomes too large and crowded. For example, the population may start to run out of food or be poisoned by its own wastes. As a result, population growth slows and population size levels off. Curve B in graph above represents this pattern of growth, which is called **logistic growth**.

At what population size does growth start to slow in the logistic model of growth? That depends on the population's carrying capacity (see graph above). The **carrying capacity** (**K**) is the largest population size that can be supported in an area without harming the environment. Population growth hits a ceiling at that size in the logistic growth model.

K-Selected and r-Selected Species

Species can be divided into two basic types when it comes to how their populations grow.

- Species that live in stable environments are likely to be *K*-selected. Their population growth is controlled by density-dependent factors. Population size is generally at or near the carrying capacity. These species are represented by curve B in the graph above.
- Species that live in unstable environments are likely to *r*-selected. Their potential population growth is rapid. For example, they have large numbers of offspring. However, individuals are likely to die young. Thus, population size is usually well below the carrying capacity. These species are represented by the lower part of curve A in the graph above.

Questions

1. What is exponential growth?

2. What is logistic growth?

3. What is the carrying capacity?

4. Define *K*- selected and *r*-selected. What is the main difference between them?

Lesson 12.2: Multiple Choice

Write	true if the statement is true or false if the statement is false.
	1. Human populations are fast growing.
	2. Stage 5 may be a new stage of the demographic transition, raising issues for some populations.
	3. The human population has had a pattern of logistic growth.
	4. The development of agriculture let humans settle down in villages and cities.
	5. In the 1700s, advances in science and technology led to lower death rates in humans.
	6. The human population is now growing by about 20,000 people a day.
	7. Today only a few countries remain in Stage 1 of the demographic transition.
	8. Stage 1 of the demographic transition has high birth and death rates, which lead to fast population growth.
	9. In stage 3 of the demographic transition, birth rate starts to fall, so population growth starts to slow.
	10. Some countries are stuck in stage 2 of the demographic transition as their birth rates are still high.
	11. By 2050, the world's population may be close to its carrying capacity.
	12. In some areas, birth rates fell when children were forced to go to school.
Less	son 12.3: Critical Reading
Name	Class Date

Demographic Transition

Major changes in the human population first began during the 1700s in Europe and North America. First death rates fell, followed somewhat later by birth rates.

Death Rates Fall

Several advances in science and technology led to lower death rates in 18th century Europe and North America:

- New scientific knowledge of the causes of disease led to improved water supplies, sewers, and personal hygiene.
- Better farming techniques and machines increased the food supply.

Read these passages from the text and answer the questions that follow.

The Industrial Revolution of the 1800s led to new sources of energy, such as coal and electricity. This increased
the efficiency of the new agricultural machines. It also led to train transport, which improved the distribution
of food.

For all these reasons, death rates fell, especially in children. This allowed many more children to survive to adulthood, so birth rates increased. As the gap between birth and death rates widened, the human population grew faster.

Birth Rates Fall

It wasn't long before birth rates started to fall as well in Europe and North America. People started having fewer children because large families were no longer beneficial for several reasons.

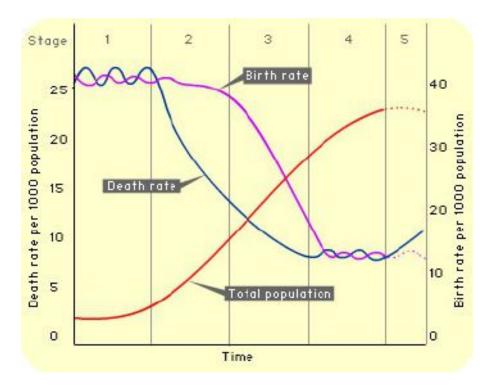

- As child death rates fell and machines did more work, farming families no longer needed to have as many children to work in the fields.
- Laws were passed that required children to go to school. Therefore, they could no longer work and contribute to their own support. They became a drain on the family's income.

Eventually, birth rates fell to match death rates. As a result, population growth slowed to nearly zero.

Stages of the Demographic Transition

These changes in population that occurred in Europe and North America have been called the **demographic transition**. The transition can be summarized in the following four stages, which are illustrated in the graph below:

- Stage 1 High birth and death rates lead to slow population growth.
- Stage 2 The death rate falls but the birth rate remains high, leading to faster population growth.
- Stage 3 The birth rate starts to fall, so population growth starts to slow.
- Stage 4 The birth rate reaches the same low level as the death rate, so population growth slows to zero.

Stages of the Demographic Transition. In the demographic transition, the death rate falls first. After a lag, the birth rate also falls. How do these changes affect the rate of population growth over time? (*Image courtesy of Charmed88 and under the public domain.*)

Questions

1. Why did death rates fall in the 1700s?

2. Why did birth rates fall in Europe and North America?

3. What is the demographic transition?

4. What are the main differences between the stages of the demographic transition?

Lesson 12.3: Multiple Choice

9. Glo	bal climate change, largely due	e to the burning of fossil fue	ls, threatens the existence of many species.
10. Ex	otic species introduced by hun	nans into new habitats have	resulted in extinction of native species.
11. P biodiversity.	'lants fixing nitrogen and mak	king it available to animals	is an important ecological service due to
12. Mo	ost species alive today have yet	t to be identified.	
Lesson 12	2.4: Critical Reading		
Name	Class	Date	
Read these po	assages from the text and answ	er the questions that follow.	

Why Is Biodiversity Important?

Human beings benefit in many ways from biodiversity. Biodiversity has direct economic benefits. It also provides services to entire ecosystems.

Economic Benefits of Biodiversity

The diversity of species provides humans with a wide range of economic benefits:

- Wild plants and animals maintain a valuable pool of genetic variation. This is important because domestic species are genetically uniform. This puts them at great risk of dying out due to disease.
- Other organisms provide humans with many different products. Timber, fibers, adhesives, dyes, and rubber are just a few examples.

- Certain species may warn us of toxins in the environment. When the peregrine falcon nearly went extinct, for example, it warned us of the dangers of DDT.
- More than half of the most important prescription drugs come from wild species. Only a fraction of species has yet been studied for their medical potential.
- Other living things provide inspiration for engineering and technology.

Ecosystem Services of Biodiversity

Biodiversity generally increases the productivity and stability of ecosystems. It helps ensure that at least some species will survive environmental change. It also provides many other ecosystem services. For example:

- Plants and algae maintain the atmosphere. During photosynthesis, they add oxygen and remove carbon
- Plants help prevent soil erosion. They also improve soil quality when they decompose.
- Microorganisms purify water in rivers and lakes. They also return nutrients to the soil.
- Bacteria fix nitrogen and make it available to plants. Other bacteria recycle the nitrogen from organic wastes and remains of dead organisms.
- Insects and hirds pollinate flowering plants, including crop plants

Lesson 12	2.5: Critical Reading		
Name	Class	Date	-
Read these pas	ssages from the text and answer	the questions that follo	vw.

The Atmosphere

The atmosphere plays an important part in maintaining Earth's freshwater supply. It is part of the water cycle. It refills lakes and rivers with precipitation. The atmosphere also provides organisms with gases needed for life. It contains oxygen for cellular respiration and carbon dioxide for photosynthesis.

Air Pollution

Earth's atmosphere is vast. However, it has been seriously polluted by human activities. **Air pollution** consists of chemical substances and particles released into the atmosphere, mainly by human actions. The major cause of outdoor air pollution is the burning of fossil fuels. Power plants, motor vehicles, and home furnaces all burn fossil fuels and contribute to the problem (see **Table 12.1**). Ranching and using chemicals, such as fertilizers, also cause air pollution. Erosion of soil in farm fields and construction sites adds dust particles to the air as well. Fumes from building materials, furniture, carpets, and paint add toxic chemicals to indoor air.

TABLE 12.1: Pollutant Problems

Pollutant	Example/Major Source	Problem
Nitrogen oxides (NO_x)	Motor vehicle exhaust	Acid Rain
Carbon monoxide (CO)	Motor vehicle exhaust	Poisoning
Carbon dioxide (CO ₂)	All fossil fuel burning	Global Warming
Smog	Coal burning	Respiratory problems; eye irritation
Ground-level ozone	Motor vehicle exhaust	Respiratory problems; eye irritation

In humans, air pollution causes respiratory and cardiovascular problems. In fact, more people die each year from air pollution than from automobile accidents. Air pollution also affects ecosystems worldwide by causing acid rain, ozone depletion, and global warming. Ways to reduce air pollution from fossil fuels include switching to nonpolluting energy sources (such as solar energy) and using less energy. What are some ways you could use less energy?

Ozone Depletion

There are two types of ozone. You can think of them as bad ozone and good ozone. Both are affected by air pollution.

- Bad ozone forms near the ground when sunlight reacts with pollutants in the air. Ground-level ozone is harmful to the respiratory systems of humans and other animals.
- Good ozone forms in a thin layer high up in the atmosphere, between 15 and 35 kilometers above Earth's surface. This ozone layer shields Earth from most of the sun's harmful UV radiation. It plays an important role in preventing mutations in the DNA of organisms.

Unfortunately, the layer of good ozone is being destroyed by air pollution. The chief culprits are chlorine and bromine gases. They are released in aerosol sprays, coolants, and other products. Loss of ozone has created an **ozone hole** over Antarctica. Ozone depletion results in higher levels of UV radiation reaching Earth. In humans, this increases skin cancers and eye cataracts. It also disturbs the nitrogen cycle, kills plankton, and disrupts ocean food webs. The total loss of the ozone layer would be devastating to most life. Its rate of loss has slowed with restrictions on pollutants, but it is still at risk.

Ouestions

- 1. Describe two important roles of the atmosphere.
- 2. What is air pollution? What is the major cause of air pollution?
- 3. List three pollutants the burning of fossil fuels adds to air. What are the sources of these three pollutants?
- 4. What is good ozone?
- 5. What are the major effects of the ozone hole?

Lesson 12.5: Multiple Choice				
Name	Class	Date		
Circle the letter of t	he correct choice.			

- a. Which of the following is a nonrenewable resource?
 - a. aluminum
 - b. wind
 - c. coal

- d. bamboo
- b. How much water on Earth is fresh, liquid water?
 - a. 1%
 - b. 2%
 - c. 5%
 - d. 10%
- c. A dead zone can form in areas where
 - a. low oxygen levels have killed all ocean life.
 - b. algal blooms have formed.
 - c. in areas of excessive nutrient-enriched runoff.
 - d. all of the above
- d. What is the major cause of outdoor air pollution?
 - a. erosion of soil in farm fields
 - b. excessive cigarette smoke
 - c. the burning of fossil fuels
 - d. excess acid rain
- e. Acid rain
 - a. can disrupt homeostasis by altering protein function.
 - b. can lower the pH of lakes.
 - c. can cause the death of plants and aquatic organisms.
 - d. all of the above
- f. The ozone hole
 - a. results in higher levels of UV radiation reaching Earth.
 - b. is located over the Arctic Circle.
 - c. is being destroyed by the greenhouse effect.
 - d. all of the above
- g. Global warming
 - a. refers to a recent decrease in Earth's average surface temperature.
 - b. has caused a decrease in the greenhouse effect.
 - c. is caused by more carbon dioxide in the atmosphere.
 - d. none of the above
- h. Effects of global climate change include
 - a. the melting of glaciers and rising sea levels.
 - b. more droughts and water shortages.
 - c. increasing severity of storms.
 - d. all of the above.

Evolution and Classification of Prokaryotes

Prokaryotes are currently placed in two domains. A domain is the highest taxon, just above the kingdom. The prokaryote domains are **Bacteria** and **Archaea**. The third domain is Eukarya. It includes all eukaryotes. Unlike prokaryotes, eukaryotes have a nucleus in their cells.

Prokaryote Evolution

It's not clear how the three domains are related. Archaea were once thought to be offshoots of Bacteria that were adapted to extreme environments. For their part, Bacteria were considered to be ancestors of Eukarya. Scientists

13.1. Prokaryotes www.ck12.org

now know that Archaea share several traits with Eukarya that Bacteria do not share (see **Table 13.1**). In what ways are Archaea and Bacteria different? In what ways are Archaea and Eukarya alike? How can this be explained? One hypothesis is that Eukarya arose when an Archaean cell fused with a Bacterial cell. The two cells became the nucleus and cytoplasm of a new Eukaryan cell. How well does this hypothesis fit the evidence in **Table 13.1**?

TABLE 13.1: Comparison of Bacteria, Archaea, and Eukarya

Characteristic	Bacteria	Archaea	Eukarya
Flagella	Unique to Bacteria	Unique to Archaea	Unique to Eukarya
Cell Membrane	Unique to Bacteria	Like Bacteria and Eu- karya	Unique to Eukarya
Protein Synthesis	Unique to Bacteria	Like Eukarya	Like Archaea
Introns	Absent in most	Present	Present
Peptidoglycan (in cell wall)	Present	Absent in most	Absent

Domain Bacteria

Bacteria are the most diverse and abundant group of organisms on Earth. They live in almost all environments. They are found in the ocean, the soil, and the intestines of animals. They are even found in rocks deep below Earth's surface. Any surface that has not been sterilized is likely to be covered with bacteria. The total number of bacteria in the world is amazing. It's estimated to be 5×10^{30} , or five million trillion. You have more bacteria in and on your body than you have body cells!

Bacteria called **cyanobacteria** are very important. They are bluish green in color because they contain chlorophyll. They make food through photosynthesis and release oxygen into the air. These bacteria were probably responsible for adding oxygen to the air on early Earth. This changed the planet's atmosphere. It also changed the direction of evolution. Ancient cyanobacteria also may have evolved into the chloroplasts of plant cells.

Domain Archaea

Archaea were first discovered in extreme environments. For example, some were found in hot springs. Others were found around deep sea vents. Such Archaea are called **extremophiles**, or "lovers of extremes." The places where some of them live are thought to be similar to the environment on ancient Earth. This suggests that they may have evolved very early in Earth's history.

Questions

1. What is a domain? What are the three domains of life?

2. List three main differences between Bacteria and Archaea.

Lesson 13.2:	Critical Reading		
Name	Class	Date	
Read these passage	es from the text and answer	r the questions that follow.	

Characteristics of Viruses

An individual virus is called a **virion**. It is a tiny particle much smaller than a prokaryotic cell. Because viruses do not consist of cells, they also lack cell membranes, cytoplasm, ribosomes, and other cell organelles. Without these structures, they are unable to make proteins or even reproduce on their own. Instead, they must depend on a host cell to synthesize their proteins and to make copies of themselves. Viruses infect and live inside the cells of living organisms. When viruses infect the cells of their host, they may cause disease. For example, viruses cause AIDS, influenza (flu), chicken pox, and the common cold.

Although viruses are not classified as living things, they share two important traits with living things. They have genetic material, and they can evolve. This is why the classification of viruses has been controversial. It calls into question just what it means to be alive. What do you think? How would you classify viruses?

13.2. Viruses www.ck12.org

Structure and Classification of Viruses

Viruses vary in their structure. The structure of a virus determines how it is classified.

Structure of Viruses

A virus particle consists of DNA or RNA within a protective protein coat called a **capsid**. The shape of the capsid may vary from one type of virus to another.

Some viruses have an envelope of phospholipids and proteins. The envelope is made from portions of the host's cell membrane. It surrounds the capsid and helps protect the virus from the host's immune system. The envelope may also have receptor molecules that can bind with host cells. They make it easier for the virus to infect the cells.

Classification of Viruses

Viruses are classified on the basis of several traits. For example, they may be classified by capsid shape, presence or absence of an envelope, and type of nucleic acid. **Table 13.2** gives examples of virus families and their traits. Most systems of classifying viruses identify at least 20 virus families, but only 4 are shown in the table. Have any of these viruses made you sick?

TABLE 13.2: Virus Classification: Four Examples

Virus Family	Capsid Shape	Envelope Present?	Type of Nucl	eic Disease Caused by a
			Acid	Virus in this Family
Adenovirus	icosahedral	no	DNA	acute respiratory

Evolution of Protists

Scientists think that protists are the oldest eukaryotes. If so, they must have evolved from prokaryotic cells. How did this happen? The endosymbiotic theory provides the most widely accepted explanation. That's because it is well supported by evidence.

Read these passages from the text and answer the questions that follow.

The First Eukaryotic Cells

According to the endosymbiotic theory, the first eukaryotic cells evolved from a symbiotic relationship between two or more prokaryotic cells. Smaller prokaryotic cells were engulfed by (or invaded) larger prokaryotic cells.

The small cells (now called endosymbionts) benefited from the relationship by getting a safe home and nutrients. The large cells (now called hosts) benefited by getting some of the organic molecules or energy released by the endosymbionts. Eventually, the endosymbionts evolved into organelles of the host cells. After that, neither could live without the other.

Some of the endosymbionts were aerobic bacteria. They were specialized to break down chemicals and release energy. They evolved into the mitochondria of eukaryotic cells. Some of the small cells were cyanobacteria. They were specialized for photosynthesis. They evolved into the chloroplasts of eukaryotic cells.

Evidence for Endosymbiotic Theory

Many pieces of evidence support the endosymbiotic theory. For example:

- Mitochondria and chloroplasts contain DNA that is different from the DNA found in the cell nucleus. Instead, it is similar to the circular DNA of bacteria.
- Mitochondria and chloroplasts are surrounded by their own plasma membranes, which are similar to bacterial membranes.
- New mitochondria and chloroplasts are produced through a process similar to binary fission. Bacteria also reproduce through binary fission.

reproduce through binary fission. • The internal structure and biochemistry of chloroplasts is very similar to that of cyanobacteria.
Questions
1. What does the endosymbiotic theory attempt to explain?
2. What benefits did the ancient endosymbionts get from their host cells?
3. What benefits did the host cells get from the endosymbionts?

4. Describe two examples of scientific evidence that support the endosyn
--

5. What does the "endo" part of endosymbiosis refer to? What does the "symbiosis" part refer to?

Lesson 14.1: Multiple Choice

Name	Class	Date

Circle the letter of the correct choice.

- a. Which of the following is **not** a principle of the endosymbiotic theory?
 - a. Mitochondria evolved from aerobic bacteria that were engulfed by a larger prokaryotic cell.
 - b. Chloroplasts evolved from endosymbiotic photosynthetic bacteria.
 - c. Prokaryotic cells evolved from eukaryotic cells.
 - d. The first eukaryotic cells evolved from a mutually beneficial relationship between two or more prokaryotic cells.
- b. How are mitochondria and chloroplasts similar?
 - a. They are both organelles in eukaryotic cells.
 - b. They are both surrounded by membranes.
 - c. They divide by binary fission.
 - d. all of the above
- c. Which location is least likely to have a population of protists?
 - a. desert
 - b. damp soil
 - c. ocean
 - d. lake
- d. Cilia
 - a. are false feet.
 - b. are short appendages that help some protists move.

- c. contain all of the DNA in a protist.
- d. all of the above
- e. The algae Spirogyra produces spores
 - a. when conditions in their environment are ideal.
 - b. to get rid of extra chloroplasts.
 - c. when conditions in their environment become unfavorable.
 - d. as a way to make food.
- f. The fusion of two Spirogyra spores to form a diploid zygote is an example of
 - a. asexual reproduction.
 - b. sexual reproduction.
 - c. binary fission.
 - d. triploid fission.
- g. Ingestive protists obtain food by
 - a. photosynthesis.
 - b. diffusion.
 - c. osmosis.
 - d. engulfing the food.
- h. Photosynthesis is
 - a. the process of engulfing food particles.
 - b. the process of transforming light energy, carbon dioxide, and water into chemical energy (food).
 - c. a type of cell movement.
 - d. none of the above.

Lesson 14.2: Critical Reading	Name	Class	Date	

Reproduction of Algae

Algae have varied life cycles. Two examples are shown in the figure below. Both cycles include phases of asexual reproduction (haploid, n) and sexual reproduction (diploid, 2n). Why go to so much trouble to reproduce? Asexual reproduction is fast, but it doesn't create new genetic variation. Sexual reproduction is more complicated and risky, but it creates new gene combinations. Each strategy may work better under different conditions. Rapid population growth is adaptive when conditions are favorable. Genetic variation helps ensure that some organisms will survive if the environment changes.

Life Cycles of Algae: Two Examples

Life Cycles of Algae: Two Examples - Zygotic meiosis and Gametic meiosis. In life cycle A, diploid (2n) zygotes undergo meiosis and produce haploid (n) gametes. The gametes undergo mitosis and produce many additional copies of themselves. How is life cycle B different from life cycle A? (*Image courtesy of CK-12 Foundation and under the Creative Commons license CC-BY-NC-SA 3.0.*)

Questions

1. What are the two types of life cycles of algae shown in the figure?

2. What is meiosis?

3. In the zygotic meiosis life cycle, what is the ploidy level (n or 2n) of the individuals? Explain your reasoning.

Lesson 14.3: Critical Reading	Name	Class Date

Reproduction of Fungi

The majority of fungi can reproduce both asexually and sexually. This allows them to adjust to conditions in the environment. They can spread quickly through asexual reproduction when conditions are stable. They can increase their genetic variation through sexual reproduction when conditions are changing and variation may help them survive.

Asexual Reproduction

Almost all fungi reproduce asexually by producing spores. A fungi spore is a haploid cell produced by mitosis from a haploid parent cell. It is genetically identical to the parent cell. Fungi spores can develop into new haploid

individuals without being fertilized.

Spores may be dispersed by moving water, wind, or other organisms. Some fungi even have "cannons" that "shoot" the spores far from the parent organism. This helps to ensure that the offspring will not have to compete with the parents for space or other resources. You are probably familiar with puffballs. They release a cloud of spores when knocked or stepped on. Wherever the spores happen to land, they do not germinate until conditions are favorable for growth. Then they develop into new hyphae. Yeasts do not produce spores. Instead, they reproduce asexually by budding. **Budding** is the pinching off of an offspring from the parent cell. The offspring cell is genetically identical to the parent.

Sexual Reproduction

Sexual reproduction also occurs in virtually all fungi. This involves mating between two haploid hyphae. During mating, two haploid parent cells fuse, forming a diploid spore called a **zygospore**. The zygospore is genetically different from the parents. After the zygospore germinates, it can undergo meiosis, forming haploid cells that develop into new hyphae.

Questions

1.	How	do	fung	i 1	benefit	from	being	able	to r	reproduce	both	asexually	and	sexually	v?

2. What are fungal spores? How are they made?

3. Why have fungi evolved mechanisms for dispersal of their spores? Name a few of these mechanisms.

4. How do many yeast reproduce asexually? What is this process called?

Name	Class	Date
------	-------	-------------

Circle the letter of the correct choice.

- a. The thread-like filaments of fungi are called
 - a. hyphae.
 - b. spores.
 - c. zygospores.
 - d. chitin.
- b. The largest known fungus is
 - a. in the Sahara desert and is 3 square feet.
 - b. in Antarctica and covers the entire surface of the continent.
 - c. in Oregon and covers 8.9 square kilometers.
 - d. none of the above.
- c. When environmental conditions are favorable, _____ is generally more beneficial for a fungal species.
 - a. asexual reproduction
 - b. sexual reproduction
 - c. moving to a new location
 - d. stopping reproduction completely
- d. Sexual reproduction of fungi involves
 - a. production of genetically identical offspring.
 - b. fusion of six haploid parent cells to form one giant cell.
 - c. fusion of two haploid parent cells to form a zygospore.
 - d. fusion of two diploid parent cells to form a tetraploid spore.

- e. Germination of a diploid zygospore followed by meiosis produces
 - a. four haploid cells.
 - b. four diploid cells.
 - c. two diploid cells.
 - d. a yeast bud.
- f. The earliest fungi evolved
 - a. independently from thousands of different ancestors.
 - b. at least 600 million years ago.
 - c. before prokaryotes.
 - d. after the first humans appeared on the earth.
- g. One way that fungi are similar to plants is
 - a. they both have cell walls made of cellulose.
 - b. they both carry out photosynthesis.
 - c. they both move rapidly from place to place.

12. having one copy of each kind of chromosome (*n*)

- d. none of the above.
- h. The phylum of fungi that is found in Antarctica, is often part of a symbiotic relationship, and is found in terrestrial ecosystems throughout the world is
 - a. protozoa.
 - b. ascomycota.
 - c. algae.
 - d. water mold.

Read t	hese passages from the text and answer the questions that follow.

Symbiotic Relationships of Fungi

Not all fungi feed on dead organisms. Many are involved in symbiotic relationships, including parasitism and mutualism.

Fungi as Parasites

In a parasitic relationship, the parasite benefits while the host is harmed. Parasitic fungi live in or on other organisms and get their nutrients from them. Fungi have special structures for penetrating a host. They also produce enzymes

that break down the host's tissues.

Parasitic fungi often cause illness and may eventually kill their host. They are the major cause of disease in agricultural plants. Fungi also parasitize animals. Fungi even parasitize humans. Did you ever have athelete's foot? If so, you were the host of a parasitic fungus. You can read more about fungi and human disease in the last lesson of this chapter.

Mutualism in Fungi

Fungi have several mutualistic relationships with other organisms. In mutualism, both organisms benefit from the relationship. Two common mutualistic relationships involving fungi are mycorrhiza and lichen.

A **mycorrhiza** is a mutualistic relationship between a fungus and a plant. The fungus grows in or on the plant roots. The fungus benefits from the easy access to food made by the plant. The plant benefits because the fungus puts out mycelia that help absorb water and nutrients. Scientists think that a symbiotic relationship such as this may have allowed plants to first colonize the land.

A **lichen** is a mutualistic relationship between a fungus and a photosynthetic organism. The other organism is usually a cyanobacterium or green alga. The fungus grows around the bacterial or algal cells. The fungus benefits from the constant supply of food produced by the photosynthesizer. The photosynthesizer benefits from the water and nutrients absorbed by the fungus.

Questions

Define parasitism
Define parasitism

2. Name and describe an example of a parasitic relationship involving a fungus.

3. Define mutualism.

1.	Name and describe an	n example of a m	utualistic relation	nship inv	olving a fungus.	

5. Why do you think that parasitism exists, when one of the organisms is harmed by the relationship?

Lesson 14.4: Multiple Choice

Name			Class	 Date	
	_	_	 _		

Circle the letter of the correct choice.

- a. Fungi are _____ like _____.
 - a. autotrophs, plants
 - b. autotrophs, animals
 - c. heterotrophs, animals
 - d. heterotrophs, plants
- b. Saprotrophs get their food
 - a. by doing photosynthesis.
 - b. from absorbing dead organic matter.
 - c. by engulfing living organisms.
 - d. by eating live plants.
- c. Some of the nutrients that plants absorb from the soil
 - a. are released into the soil from dead organic matter by fungi.
 - b. are cellulose and lignin.
 - c. are saprotrophs engulfed by the plant's leaves.
 - d. none of the above
- d. Fungal hyphae
 - a. are long filaments that aid in absorption of water and minerals.
 - b. can penetrate deep into organic matter.
 - c. release enzymes that can digest organic matter such as cellulose and lignin.

- d. all of the above
- e. Parasitic fungi
 - a. help their host.
 - b. harm their host.
 - c. carry out photosynthesis.
 - d. make lignin.

f. Mycorrhiza is

- a. a parasitic relationship between a plant and an animal.
- b. a mutualistic relationship between a plant and an animal.
- c. a mutualistic relationship between a plant and a fungus.
- d. a parasitic relationship between a plant and a fungus.

g. A lichen is

- a. a parasitic relationship between a plant and an animal.
- b. a parasitic relationship between a plant and a fungus.
- c. a mutualistic relationship between an animal and a fungus.
- d. a mutualistic relationship between a fungus and a photosynthetic organism.

h. Penicillin is

- a. an antibiotic produced by plants.
- b. an antibiotic produced by a fungus.
- c. a parasite of some insects.

Fungi and Human Disease

Fungi cause human illness in three different ways: poisonings, parasitic infections, and allergic reactions. Fungal poisoning and fungal parasites are described below.

Fungal Poisoning

Many fungi protect themselves from parasites and predators by producing toxic chemicals. If people eat toxic fungi, they may experience digestive problems, hallucinations, organ failure, and even death. Most cases of mushroom poisoning are due to mistaken identity. That's because many toxic mushrooms look very similar to safe, edible mushrooms.

Fungal Parasites

Some fungi cause disease when they become human parasites. Two examples are fungi in the genera *Candida* and *Trichophyton*.

- *Candida* are yeast that cause **candidiasis**, commonly called a "yeast infection." The yeast can infect the mouth or the vagina (in females). If yeast enter the blood, they cause a potentially life threatening illness. However, this is rare, except in people with a depressed immune system.
- *Trichophyton* are fungi that cause **ringworm**. This is a skin infection characterized by a ring-shaped rash. The rash may occur on the arms, legs, head, neck, or trunk. The same fungi cause **athlete's foot** when they infect the skin between the toes. Athlete's foot is the second most common skin disease in the U.S.

Bee Peppered with Yellow Pollen Grains

(Pollen image copyright MichaelTaylor, 2010, and bee image copyright Joseph Calev, 2010. Both images used under licenses from Shutterstock.com.)

Seed Plants Emerge

For reproduction, early vascular plants still needed moisture. Sperm had to swim from male to female reproductive organs for fertilization. Spores also needed some water to grow and often to disperse as well. Of course, dryness and other harsh conditions made it very difficult for tiny new offspring plants to survive. With the evolution of seeds in vascular plants, all that changed. Seed plants evolved a number of adaptations that made it possible to reproduce without water. As a result, seed plants were wildly successful. They exploded into virtually all of Earth's habitats.

Why are seeds so adaptive on land? A seed contains an embryo and a food supply enclosed within a tough coating. An embryo is a zygote that has already started to develop and grow. Early growth and development of a plant embryo in a seed is called germination. The seed protects and nourishes the embryo and gives it a huge head start in the "race" of life. Many seeds can wait to germinate until conditions are favorable for growth. This increases the offspring's chance of surviving even more.

Other reproductive adaptations that evolved in seed plants include ovules, pollen, pollen tubes, and pollination by animals.

- An ovule is a female reproductive structure in seed plants that contains a tiny female gametophyte. The gametophyte produces an egg cell. After the egg is fertilized by sperm, the ovule develops into a seed.
- A grain of pollen is a tiny male gametophyte enclosed in a tough capsule (see the figure above). It carries sperm to an ovule while preventing it from drying out. Pollen grains can't swim, but they are very light, so the wind can carry them. Therefore, they can travel through air instead of water.
- Wind-blown pollen might land anywhere and be wasted. Another adaptation solved this problem. Plants evolved traits that attract specific animal pollinators. Like the bee in the figure above, a pollinator picks up pollen on its body and carries it directly to another plant of the same species. This greatly increases the chance that fertilization will occur.
- Pollen also evolved the ability to grow a tube, called a pollen tube, through which sperm could be transferred directly from the pollen grain to the egg. This allowed sperm to reach an egg without swimming through a film of water. It finally freed up plants from depending on moisture to reproduce.

Questions

1. Why did early vascular plants need to live in environment where there was plenty of water?

2. What main advantage do seed plants have over the early spore-producing plants?

3. Define what a plant seed is.

4. What is the function of a plant ovule?

5. How did the evolution of pollen benefit land plants?

Lesson 15.1: Multiple Choice

Lesson 15.2: C	Critical Reading	
Name	Class	Date
	from the text and answer	

Evolution of Vascular Plants

The first vascular plants evolved about 420 million years ago. They probably evolved from moss-like bryophyte ancestors, but they had a life cycle dominated by the diploid sporophyte generation. As they continued to evolve, early vascular plants became more plant-like in other ways as well.

Vascular plants evolved true roots made of vascular tissues. Compared with rhizoids, roots can absorb more
water and minerals from the soil. They also anchor plants securely in the ground, so plants can grow larger
without toppling over.

- Vascular plants evolved stems made of vascular tissues and lignin. Because of lignin, stems are stiff, so plants can grow high above the ground where they can get more light and air. Because of their vascular tissues, stems keep even tall plants supplied with water so they don't dry out in the air.
- Vascular plants evolved leaves to collect sunlight. At first, leaves were tiny and needle-like, which helped reduce water loss. Later, leaves were much larger and broader, so plants could collect more light.

With their vascular tissues and other adaptations, early vascular plants had the edge over nonvascular plants. They could grow tall and take advantage of sunlight high up in the air. Bryophytes were the photosynthetic pioneers onto land, but early vascular plants were the photosynthetic pioneers into air.

land, but early vascular plants were the photosynthetic pioneers into air.
Questions
1. How and when did vascular plants evolve?
2. What advantages do roots have compared to rhizoids?
3. What advantages do stems give vascular plants?
er min au miniges de stema grande.

4. Why was evolution of leaves successful?

5. If vascular plants have so many advantages, why do you think nonvascular plants still exist on earth today?

Multiple Choice

Circle the letter of the correct choice.

- a. Skunk cabbage has evolved stinky flowers because
 - a. the smell prevents other plants from growing nearby all year long.
 - b. all yellow flowers smell bad.
 - c. the odor attracts pollinators.
 - d. the odor repels pollinators.
- b. Which of the following is **not** a characteristic of most plants?
 - a. carries out photosynthesis
 - b. has cell walls made of cellulose
 - c. has yellow flowers
 - d. has specialized reproductive organs
- c. Much of the oxygen in the earth's atmosphere
 - a. is produced as a waste product of cellular respiration in plants.
 - b. is released as a byproduct of photosynthesis.
 - c. is produced as a waste product of cellular respiration in animals.
 - d. is produced by tree frogs.
- d. The mature sporophyte of a fern
 - a. produces haploid spores by meiosis.
 - b. produces diploid spores by meiosis.
 - c. produces diploid spores by mitosis.
 - d. produces haploid spores by mitosis.
- e. Fusion of male and female gametes in plants produces
 - a. a eudicot stamen.
 - b. a style.
 - c. a haploid spore.
 - d. a diploid embyro.
- f. Marine plants
 - a. have always been the dominant organisms of the oceans.
 - b. evolved after land plants.
 - c. are restricted to the water closer to the air, so they can get sufficient light for photosynthesis.
 - d. do not need to photosynthesize.
- g. The vascular tissue that transports water and minerals from the soil to the rest of the plant is the
 - a. phloem.

- b. phlegm. c. leaf. d. xylem. h. The vascular tissue that transports sugars from photosynthetic tissues to the rest of the plant is a. phloem. b. phlegm. c. leaf. d. xylem. i. In most land plants, the _____ generation is the dominant one. a. diploid sporophyte b. diploid gametophyte c. haploid sporophyte d. haploid gametophyte j. In seed plants, the _____ helps transfer of sperm from the pollen grain to the egg. a. sepal b. petal c. tuberous ovule
- k. The scales of pine cones are
 - a. always green.

d. pollen tube

- b. modified roots.
- c. modified leaves.
- d. modified stems.
- 1. Plants that make flowers are called
 - a. gymnosperms.
 - b. byrophytes.
 - c. gametophytes.
 - d. angiosperms.
- m. The class of plants that has vascular tissue and reproduces with spores is the
 - a. clubmosses.
 - b. liverworts.
 - c. flowering plants.
 - d. conifers.
- n. The embryonic stem in a seed is called the
 - a. radicle.
 - b. hypocotyl.
 - c. seed coat.
 - d. endosperm.
- o. Pollen contains
 - a. male gametes.
 - b. female gametes.
 - c. fruits.
 - d. a stigma.

True or False

Write true if the statement is true or false if the statement is false.

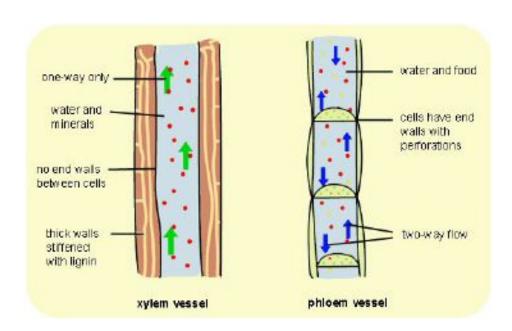

16. Plants are a direct or indirect source of food for most organisms living on earth.
17. A ripened ovary becomes a pollen grain.
18. Cross-pollination decreases genetic diversity.
19. Monocot embryos have one cotyledon.
20. Currently on earth, there are many more gymnosperm species than angiosperm species.
Fill in the Blanks
Fill in the blank with the term that best completes the sentence.
21. Switching between a haploid gametophyte stage and a diploid sporophyte stage is called
22 gives plant stems stiffness and helps protect plants against predators.
23. Nonvascular plants use for absorbing water.
24. Asexual reproduction from stems, leaves, or roots is called
25 occurs when a growing plant embryo bursts through the seed coat.
26. Liverworts, hornworts, and mosses are all plants.
27. Another name for vascular plants is
28 stores food in seed plants.
29. In a flower the contains the stigma, style, and ovary.

Short Answer

Answer each question in the space provided.

30. The _____ protects the seed.

Refer to the figure below to answer questions 31 and 32.

(Xylem and phloem image is courtesy of Jesse Landy and under the Creative Commons license CC-BY-SA 3.0.)

31. What is the function of xylem vessels? How does their structure support their function?

32. What is the function of phloem vessels? How does their structure support their function?

33. How did plants and pollinators co-evolve? Describe a specific example.

Write true if the stateme		
1. An organ is a	structure made of only	ly one type of tissue.
2. A tissue is ma	de of a group of cells	s that have the same job.
3. Instead of hav	ing a plasma membra	ane, plant cells have a cell wall.
4. Plant cells are	prokaryotic.	
5. The main fund	tion of plastids is to r	maintain pressure against the cell wall.
6. A plant's centr	al vacuole is typically	ly large.
7. The plant cell	wall is located just in	nside the plant's plasma membrane.
8. Plant cells wal	ls can contain both ce	rellulose and lignin.
9. Some types of	parenchymal cells are	re photosynthetic cells.
10. Cell walls of	sclerenchyma are ver	ry thick.
11. Xylem and p	hloem are types of de	ermal tissue.
12. The plant cut	icle protects and wate	erproofs the above-ground parts of the plant.
13. Most plants g	grow only during a ver	ery short period during their lifetime.
14. Cell division	decreases the number	er of cells in a plant.
15. Meristem is 1	nade of differentiated	d cells.
Lesson 16.1: Crit	ical Reading	
Name	Class	Date

Plant Tissues

All three types of plant cells are found in most plant tissues. Three major types of plant tissues are dermal, ground, and vascular tissues.

Dermal Tissue

Dermal tissue covers the outside of a plant in a single layer of cells called the epidermis. You can think of the epidermis as the plant's skin. It mediates most of the interactions between a plant and its environment. Epidermal cells secrete a waxy substance called cuticle, which coats, waterproofs, and protects the above-ground parts of plant. Cuticle helps prevent water loss, abrasions, infections, and damage from toxins.

Ground Tissue

Ground tissue makes up much of the interior of a plant and carries out basic metabolic functions. Ground tissue in stems provides support and may store food or water. Ground tissues in roots may also store food.

Vascular Tissue

Vascular tissue runs through the ground tissue inside a plant. It consists of xylem and phloem, which transport fluids. Xylem and phloem are packaged together in bundles.

Questions

1	Define	the	term	ticcue	28	used	in	this	passage.
1.	Denne	uic	willi	ussuc	as	uscu	ш	ums	passage.

2. What is a plant's epidermis? What is its function?

3. Describe the functions of ground tissue.

4. Why are xylem and phloem bundled together?

5. Do you think that all plants have these three types of tissue? Why or why not?

Lesson 16.1: Multiple Choice

Name	Class	Date	

Circle the letter of the correct choice.

- a. Which of the following types of cells would be best at storing food for a plant?
 - a. parenchymal
 - b. sclerenchymal
 - c. cell in a flower petal
 - d. prokaryotic
- b. The organelle that maintains pressure against the cell wall, so that the plant cell keeps it shape, is the
 - a. central vacuole.
 - b. rough endoplasmic reticulum.
 - c. smooth endoplasmic reticulum.
 - d. nucleus.
- c. A membrane-bound organelle that contains DNA is a
 - a. Golgi body.
 - b. smooth endoplasmic reticulum.
 - c. chloroplast.
 - d. cell wall.
- d. The plant cuticle
 - a. coats the surface of the root.
 - b. is made by ground tissue.
 - c. transports sugars throughout the plant.
 - d. is made by epidermal cells.
- e. Xylem and phloem are
 - a. dermal tissue.
 - b. ground tissue.
 - c. vascular tissue.
 - d. epidermal tissue.
- f. The meristem consists of
 - a. cells with a thick cuticle.
 - b. differentiated cells.
 - c. undifferentiated cells.

- d. all of the above.
- g. Plant roots can grow to become wider
 - a. by cell division of differentiated root cells.
 - b. from water absorption in the leaves.
 - c. when the cuticle is made.
 - d. through cell division in a root meristem.
- h. When a single cell divides once by mitosis, the product is
 - a. a single cell with half the DNA of the original cell.
 - b. two cells.
 - c. four cells.
 - d. eight cells.

h. ground tissue

Root Structures and Functions

Read these passages from the text and answer the questions that follow.

The tip of a root is called the root cap. It consists of specialized cells that help regulate primary growth of the root at the tip. Above the root cap is primary meristem, where growth in length occurs.

Above the meristem, the rest of the root is covered with a single layer of epidermal cells. These cells may have root hairs that increase the surface area for the absorption of water and minerals from the soil. Beneath the epidermis is ground tissue, which may be filled with stored starch. Bundles of vascular tissues form the center of the root. Waxy layers waterproof the vascular tissues so they don't leak, making them more efficient at carrying fluids. Secondary meristem is located within and around the vascular tissues. This is where growth in thickness occurs.

The structure of roots helps them perform their primary functions. What do roots do? They have three major jobs: absorbing water and minerals, anchoring and supporting the plant, and storing food.

- · Absorbing water and minerals: Thin-walled epidermal cells and root hairs are well suited to absorb water and dissolved minerals from the soil. The roots of many plants also have a mycorrhizal relationship with fungi for greater absorption.
- Anchoring and supporting the plant: Root systems help anchor plants to the ground, allowing plants to grow tall without toppling over. A tough covering may replace the epidermis in older roots, making them rope-like and even stronger.

Storing food: In many plants, ground tissues in roots store food produced by the leaves during photosynthem.
Questions
1. Picture a plant's root cap. What additional function might it have that is not described in the above passage?
2. How do root hairs increase the surface area for water and mineral absorption?
3. What is a function of the ground tissue of a root?

4. What are the three main functions of roots?

LC33UII	10.2.	WILLI	PIE	CII	OICC

Name	Class	Date

Circle the letter of the correct choice.

- a. The main difference between a taproot system and a fibrous root system is that
 - a. taproots can store a lot of food, while fibrous roots do not.
 - b. taproots absorb water, while fibrous roots do not.
 - c. fibrous roots can access water sources deep under the ground, while taproots cannot.
 - d. fibrous roots have an epidermal cell layer, while taproots do not.
- b. Roots grown downward because
 - a. they have vascular bundles.
 - b. they grow opposite to the force of gravity.
 - c. they grow away from water sources.
 - d. there are gravity-sensing cells in the root cap.
- c. The xylem of the vascular tissue in the root
 - a. carries sugars from the leaves to the roots for storage.
 - b. carries water and minerals from the root up to the stem.
 - c. detects gravity and causes the root to grow downward.
 - d. none of the above
- d. In stems, the _____ meristem is responsible for growth in length, and the _____ meristem is primarily responsible for growth in width.
 - a. secondary, primary
 - b. primary, secondary
 - c. node, epidermal

- d. epidermal, node
- e. A main function of the leaf petiole is
 - a. to extend the leaf blade away from the stem so the blade can collect sufficient sunlight.
 - b. to keep the leaf away from the secondary meristem of the stem.
 - c. to produce pollen.
 - d. none of the above.
- f. Very thick stems are specialized for
 - a. clinging and climbing.
 - b. strength and support.
 - c. storing water or food.
 - d. photosynthesis.
- g. Leaves arranged in whorls are optimized to
 - a. collect sunlight from all directions.
 - b. to increase resistance to wind.
 - c. to increase water loss.
 - d. to increase food storage capacity.
- h. The air spaces in the leaf interior

Lesson 16.2: Vocabulary I

- a. block gas exchange between the mesophyll cells and the environment.
- b. make the leaf weigh more than a leaf packed tightly with cells.
- c. make the leaf weigh less than a leaf packed tightly with cells.
- d. carry out most of the photosynthesis in the leaf.

Name _.	Class Date
Match	the vocabulary word with the proper definition.
Defini	tions
	1. photosynthetic leaf cells
	2. increases the surface area for absorbing water in the root
	3. the type of roots a plant has
	4. a plant that keeps its leaves for more than one year
	5. a leaf pore flanked by two guard cells
	6. a plant that loses its leaves yearly and grows new ones
	7. a thick primary root often growing deep into the soil
	8. the outermost woody covering of a stem
	9. the tip of a root
	10. the part of a stem from which secondary branches grow
	11. the leaf part that supports and displays the leaf blade
	12. has multiple, spreading roots without a main primary roo

- a. bark
- b. deciduous plant
- c. evergreen plant
- d. fibrous root
- e. mesophyll
- f. node
- g. petiole
- h. root cap
- i. root hair
- j. root system
- k. stomata
- 1. taproot

Lesson 16.2: Vocabulary II

[ame Class Date
ill in the blank with the appropriate term.
. The leaf, which is connected to the leaf petiole, is a very important photosynthetic part of a plant.
. A can grow deep into the ground to access water, and can also store food for the plant.
. There are two main types of in plants for absorbing water and minerals.
. In the fall, lose their leaves.
. The can close to reduce water loss from the leaf.
. Even though part of it is nonliving, functions to protect the living parts of the stem.
consists of photosynthetic cells located in between the upper and lower epidermis of a leaf.
. Plants with a root system are less securely anchored to the ground.
. A pine tree is an example of a(n)
0. Leaves and secondary stems grow out of stem
1 are long, thin cells in the epidermal cell layer of roots.
2. The leaf is attached to the stem via a(n)
esson 16.2: Critical Writing

Thoroughly answer the question below. Use appropriate academic vocabulary and clear and complete sentences.

Name_____ Class____ Date____

Not all plant stems are the same. Name and describe three different stem types of plants and how they adapt a plant to its environment.

16.3 Variation in Plant Life Cycles

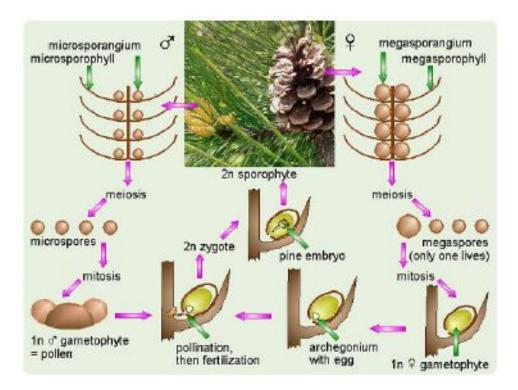

Lesson 16.3: T	rue or False	
Name	Class	Date
Write true if the state	ement is true or false if th	he statement is false.
1. A plant spe	ecies has either a haploid g	gametophyte phase, or a diploid sporophyte phase, b
2. Meiosis in	the sporangium produces	s haploid spores.
3. A haploid	spore develops into a hapl	ploid gametophyte.
4. Fertilizatio	n of gametes produces a h	haploid zygote.
5. The domin	ant generation in vascular	ar plants is the gametophyte.
6. In nonvasc	ular plants, archegonia arc	re the male reproductive organs.
7. Ferns are s	eedless vascular plants.	
8. A new spor	rophyte fern plant develop	ops from a fertilized egg and sperm.
9. Gymnospe	rms are flowering vascula	ar plants.
10. Cones are	the reproductive structure	re in gymnosperms.
11. The dots	on the back of fern fronds	s are sporangia.
12. Gymnosp	erms have male cones and	nd female cones.
13. Angiospe	rms are flowering nonvaso	scular plants.
14. Angiospe	rms produce pollen.	
15. Fruit deve	elops from a ripened ovary	ry surrounding a seed.
Lesson 16.3: C	Critical Reading	
Name	Class	Date
Name	Class	Date

Gymnosperms are vascular plants that produce seeds in cones. Examples include conifers, such as pine and spruce trees. The gymnosperm life cycle has a dominant sporophyte generation. Both gametophytes and the next generation's new sporophytes develop on the sporophyte parent plant. A diagram of a gymnosperm life cycle is

310

shown below.

Life Cycle of Gymnosperms

(Image courtesy of APS and under the Creative Commons license CC-BY-SA 3.0.)

Cones form on a mature sporophyte plant. Inside male cones, male spores develop into male gametophytes. Each male gametophyte consists of several cells enclosed within a grain of pollen. Inside female cones, female spores develop into female gametophytes. Each female gametophyte produces an egg inside an ovule.

Pollination occurs when pollen is transferred from a male to female cone. If sperm then travel from the pollen to an egg so fertilization can occur, a diploid zygote results. The zygote develops into an embryo within a seed, which forms from the ovule inside the female cone. If the seed germinates, it may grow into a mature sporophyte tree, which repeats the cycle.

Questions

1. In a complete sentence, define gymnosperm.

3. Where do male and female gametophytes develop in gymnosperms?

4. Describe sexual reproduction in gymnosperms.

5. What are the advantages of sexual reproduction?

Lesson 16.3: Multiple Choice

Name_____ Class____ Date____

Circle the letter of the correct choice.

- a. In plants, sperm and eggs are produced by
 - a. mitosis in reproductive organs of the gametophyte.
 - b. mitosis in the diploid sporophyte.
 - c. meiosis in the zygote.
 - d. mitosis of root hairs.
- b. The gametophyte generation is dominant in
 - a. pine trees, spruce trees, and maple trees.
 - b. clubmosses, ginkgo, and cycads.
 - c. hornworts, liverworts, and mosses.
 - d. all of the above.
- c. In nonvascular plants, eggs are produced
 - a. by the same structure that produces sperm.
 - b. in female reproductive organs called archegonia.
 - c. in male reproductive organs called archegonia.
 - d. by mitosis in the diploid sporophyte.
- d. In seedless vascular plants,
 - a. spores fuse to form a zygote.
 - b. there are no antheridia.
 - c. the haploid gametophyte generation dominates.
 - d. the diploid sporophyte generation dominates.
- e. Gymnosperms are
 - a. seedless nonvascular plants.
 - b. flowering nonvascular plants.
 - c. vascular plants producing flowers.
 - d. vascular plants producing seeds in cones.
- f. Gymnosperms reproduce using
 - a. xylem and phloem.
 - b. pollen and female cones.
 - c. flowers and wind.
 - d. antheridia and spores.
- g. In pollen grains, _____ are formed.
 - a. eggs
 - b. sperm
 - c. female reproductive structures
 - d. ovules
- h. In angiosperms, the _____ produces eggs via meiosis.
 - a. stamen
 - b. pollen tube
 - c. pistil
 - d. seed

Adaptations to Extreme Dryness

Read these passages from the text and answer the questions that follow.

Plants that live in extremely dry environments have the opposite problem: how to get and keep water. Plants that are adapted to very dry environments are called xerophytes. Their adaptations may help them increase water intake, decrease water loss, or store water when it is available.

The saguaro cactus pictured in **Figure 16.24** in your book has adapted in all three ways. When it was still a very small plant, just a few inches high, its shallow roots already reached out as much as 2 meters (7 feet) from the base of the stem. By now, its root system is much more widespread. It allows the cactus to gather as much moisture as possible from rare rainfalls. The saguaro doesn't have any leaves to lose water by transpiration. It also has a large,

barrel-shaped stem that can store a lot of water.	Thorns protect the stem	n from thirsty animal	s that might try to get at
the water inside.			

Questions

1. What is a main challenge faced by plants that live in a desert?

2. Name three strategies used by xerophytes to adapt to their environment.

3. In what type of environment does a saguaro cactus live?

4. How does the saguaro cactus take advantage of rare, brief rainfall?

5. How does the structure of the saguaro cactus stem benefit the plant?

Lesson	16.4:	Multip	le C	Choice
--------	-------	--------	------	--------

Name	Class	Date

Circle the letter of the correct choice.

- a. Which of the following is **not** a typical characteristic of aquatic plants?
 - a. They live in the water.
 - b. They have extensive vascular tissues for transporting water.
 - c. Their leaves collect sunlight.
 - d. They do not need roots.
- b. Desert plants adapt to a limited water supply by
 - a. conserving water.
 - b. storing water.
 - c. efficiently absorbing water when it is available.
 - d. all of the above
- c. Which of the following plants is an epiphyte?
 - a. orchid
 - b. saguaro cactus
 - c. cattail
 - d. water lily
- d. Which kind of plant is best adapted for life in the tropical rainforest?
 - a. saguaro cactus
 - b. epiphyte
 - c. oak tree
 - d. all of the above
- e. The leaves of which plant are shaped to collect and store a lot of water?
 - a. water lily
 - b. cattail
 - c. saguaro cactus
 - d. bromeliad
- f. Growth toward the force of gravity is called
 - a. auxin.
 - b. geotropism.
 - c. phototropism.
 - d. thigmotropism.

- g. Growth toward the light is called
 - a. auxin.
 - b. geotropism.
 - c. phototropism.
 - d. thigmotropism.
- h. Plants often enter dormancy
 - a. when rainfall is abundant.
 - b. just before they form flowers.
 - c. during winter.
 - d. in the spring.

Evolution of Amniotes

Read these passages from the text and answer the questions that follow.

Amphibians were the first animals to have true lungs and limbs for life on land. However, they still had to return to water to reproduce. That's because their eggs lacked a waterproof covering and would dry out on land. The first fully terrestrial vertebrates were amniotes. Amniotes are animals that produce eggs with internal membranes. The membranes let gases but not water pass through. Therefore, in an amniotic egg, an embryo can breathe without drying out. Amniotic eggs were the first eggs that could be laid on land. The earliest amniotes evolved about 350 million years ago. They may have looked like the animal shown below. Within a few million years, two important amniote groups evolved: synapsids and sauropsids. Synapsids evolved into mammals. The sauropsids gave rise to reptiles, dinosaurs, and birds.

Early Amniote. The earliest amniotes probably looked something like this. They were reptile-like, but not actually reptiles. Reptiles evolved somewhat later. (*Image courtesy of ArthurWeasley and under the Creative Commons license CC-BY-SA 3.0.*)

Questions

1. Why was the evolution of amphibians notable? What did they pioneer?

2. What characteristic of amphibians necessitates that they live near water?

3. Define amniote.

4. What reproductive advantage do amniotes have over pre-amniotes?

17.1. Overview of Animals www.ck12.org

5. What are the important animal groups that evolved from amniotes? What in turn, evolved from these groups?

	12. Some invertebrates have an internal skeleton.	
	13. The outside of an animal is formed from the ectoderm.	
	14. A partial coelom is called a psuedocoelom.	
	15. Complete digestion is less efficient than incomplete digestion because most animals eat too much for	od.
Less	son 17.2: Critical Reading	
Name	Class Date	
Read	these passages from the text and answer the questions that follow.	

Complete Digestive System

Early invertebrates had an incomplete digestive system. There was just one opening for the mouth and anus. Ancestors of modern roundworms were the first animals to evolve a complete digestive system. With a separate mouth and anus, food could move through the body in just one direction. This made digestion more efficient. An animal could keep eating while digesting food and getting rid of waste. Different parts of the digestive tract could also become specialized for different digestive functions. This led to the evolution of digestive organs.

Pseudocoelom and Coelom

Ancestors of roundworms also evolved a pseudocoelom. This is a partial body cavity that is filled with fluid. It allows room for internal organs to develop. The fluid also cushions the internal organs. The pressure of the fluid within the cavity provides stiffness. It gives the body internal support, forming a hydrostatic skeleton. It explains why roundworms are round and flatworms are flat. Later, a true coelom evolved. This is a fluid-filled body cavity, completely enclosed by mesoderm. It lies between the digestive cavity and body wall (see the figure below). Invertebrates with a true coelom include mollusks and annelids.

Lesson 18.1: C	Critical Reading	
Name	Class	Date
		r the questions that follow.

Ecology of Flatworms

Both flukes and tapeworms are parasites with vertebrate hosts, including human hosts. Flukes live in the host's circulatory system or liver. Tapeworms live in the host's digestive system. Usually, more than one type of host is required to complete the parasite's life cycle. Look at the life cycle of the liver fluke in the diagram below. As an adult, the fluke has a vertebrate host. As a larva, it has an invertebrate host. If you follow the life cycle, you can see how each host becomes infected so the fluke can continue its life cycle.

Life Cycle of the Sheep Liver Fluke. The sheep liver fluke has a complicated life cycle with two hosts. How could such a complicated way of life evolve? (Image courtesy of the Centers for Disease Control and Prevention and under the public domain.)

Questions

1. What are some major characteristics shared by tapeworms and flukes?

2. Where does the fluke described in the reading above live in humans?

3. What is another host of the liver fluke?

4 When does the fluke live in this	hoot'

5. How does it get from the human host to this host?

Lesson 18	3.1: Critic	cal Writing
-----------	-------------	-------------

Name	Class	Date

Thoroughly answer the question below. Use appropriate academic vocabulary and clear and complete sentences.

Corals live in colonies in shallow water in the tropics. They participate in a mutualistic relationship with algae. The algae live inside the coral. Based on this information, how do you think the coral and the algae benefit from this relationship?

18.2 Mollusks and Annelids

Name	Class	Date
Write true if the stat	tement is true or false if th	he statement is false.
1. Mollusks	were the first vertebrates t	to evolve.
2. Earthworn	ns are mollusks.	
3. The hard o	outer shell of mollusks is i	made by the mantle.
4. Mollusks	can be filter feeders.	
5. The radula	of mollusks excretes was	ste from the mollusk's body.
6. Mollusks l	nave an incomplete digest	tive system with one opening.
7. Gills funct	tion to digest food.	
8. Mollusks l	have one or two hearts.	
9. Bivalves a	re typically very fast mov	ring.
10. The phyl	um Annelida consists of t	unsegmented worms.
11. Some ani	nelids live in the ocean.	
12. Annelids	have a true coelom.	
13. Annelids	have an open circulatory	system.
14. Snails are	e annelids.	
15 In some	species of annelids, the sa	me individual can make both female and male gametes.

Read these passages from the text and answer the questions that follow.

Annelids range in length from less than 1 millimeter to over 3 meters. They never attain the large size of some mollusks. Like mollusks, however, they have a coelom. In fact, the annelid coelom is even larger, allowing greater development of internal organs. Annelids have other similarities with mollusks, including:

- A closed circulatory system (like cephalopods).
- An excretory system consisting of tubular nephridia.
- A complete digestive system.
- A brain.
- Sensory organs for detecting light and other stimuli.
- Gills for gas exchange (but many exchange gas through their skin).

Questions

1. How large are annelids?

2. Do annelids have a coelom?

3. What kind of circulatory system do annelids have?

4. How do annelids exchange gases with their environment?

5. What is the function of gills?

Lesson	18.2:	Multip	ole	Choice

Structure and Function of Arthropods

Arthropods range in length from about 1 millimeter to 4 meters (about 13 feet). They have a segmented body with a hard exoskeleton. They also have jointed appendages. The body segments are the head, thorax, and abdomen. In some arthropods, the head and thorax are joined together as a cephalothorax.

The arthropod exoskeleton consists of several layers of cuticle. The exoskeleton prevents water loss and gives support and protection. It also acts as a counterforce for the contraction of muscles. The exoskeleton doesn't grow as the animal grows. Therefore, it must be shed and replaced with a new one periodically throughout life. This is called molting. The jointed appendages of arthropods may be used as legs for walking. Being jointed makes them more flexible. Try walking or climbing stairs without bending your knees, and you'll see why joints are helpful. In

most arthropods, the appendages on the head have been modified for other functions. The figure below shows some of head appendages found in arthropods. Sensory organs such as eyes are also found on the head.

Characteristics of Chordates

Chordates have three embryonic cell layers. They also have a segmented body with a coelom and bilateral symmetry. Chordates have a complete digestive system and a closed circulatory system. Their nervous system is centralized. There are four additional traits that are unique to chordates. These four traits, shown in the diagram below, define the chordate phylum.

- Post-anal tail: The tail is opposite the head and extends past the anus.
- Dorsal hollow nerve cord: The nerve cord runs along the top, or dorsal, side of the animal. (In nonchordate animals, the nerve cord is solid and runs along the bottom).

- Notochord: The notochord lies between the dorsal nerve cord and the digestive tract. It provides stiffness to counterbalance the pull of muscles.
- Pharyngeal slits: Pharyngeal slits are located in the pharynx. This is the tube that joins the mouth to the digestive and respiratory tracts.

Body Plan of a Typical Chordate. The body plan of a chordate includes a post-anal tail, notochord, dorsal hollow nerve cord, and pharyngeal slits. (*Image courtesy of CK-12 Foundation and under the Creative Commons license CC-BY-NC-SA 3.0.*)

	8. There are about 50,000 vertebrate species.
	9. Mammals and birds both evolved from reptile-like ancestors.
	10. Amphibians evolved from reptiles, which evolved from fish.
	11. The earliest vertebrates were jawless fish.
	12. Reptiles were the first vertebrates to live on land.
	13. The earliest vertebrates lived between 500 and 600 million years ago.
	14. The first vertebrates to lay amniotic eggs were amphibians.
	15. Endothermy means regulating body temperature from the outside through behavioral changes.
Less	on 19.1: Critical Reading
Name_	Class Date
Read ti	hese passages from the text and answer the questions that follow.

Characteristics of Vertebrates

The main distinguishing feature of vertebrates is their vertebral column, or backbone. The backbone runs from the head to the tail along the dorsal (top) side of the body. The vertebral column is the core of the endoskeleton. It allows a vertebrate to hold its shape. It also houses and protects the spinal (nerve) cord that passes through it. The vertebral column is made up of repeating units called **vertebrae** (singular, vertebra). In many species, there are shock-absorbing discs between the vertebrae to cushion them during movement.

Other Vertebrate Traits

There are several additional traits found in virtually all vertebrates.

- Vertebrates have a system of muscles attached to the endoskeleton to enable movement. Muscles control movement by alternately contracting (shortening) and relaxing (lengthening). Generally, muscles work together in opposing pairs.
- Vertebrates have a closed circulatory system with a heart. Blood is completely contained within blood vessels that carry the blood throughout the body. The heart is divided into chambers that work together to pump blood. There are between two and four chambers in the vertebrate heart. With more chambers, there is more oxygen in the blood and more vigorous pumping action.
- Most vertebrates have skin covered with scales, feathers, fur, or hair. These features serve a variety of functions, such as waterproofing and insulating the body.
- Vertebrates have an excretory system that includes a pair of kidneys. **Kidneys** are organs that filter wastes from blood so they can be excreted from the body.
- Vertebrates have an endocrine system of glands that secrete hormones. Hormones are chemical messengers that control many body functions.
- Vertebrates have an adaptive immune system. The **immune system** is the organ system that defends the body from pathogens and other causes of disease. Being adaptive means that the immune system can *learn* to recognize specific pathogens. Then it can produce tailor-made chemicals called antibodies to *attack* them. This allows the immune system to launch a rapid attack whenever the pathogens invade the body again.
- Vertebrates have a centralized nervous system. The nervous system consists of a brain in the head region. It also includes a long spinal cord that runs from the brain to the tail end of the backbone. Long nerve fibers extend from the spinal cord to muscles and organs throughout the body.

Lesson 1	19.2: Critical Reading		
Name	Class	Date	

Structure and Function in Fish

Fish show great diversity in body size. They range in length from about 8 millimeters (0.3 inches) to 16 meters (about 53 feet). Most are ectothermic and covered with scales. Scales protect fish from predators and parasites and reduce friction with the water. Multiple, overlapping scales provide a flexible covering that allows fish to move easily while swimming.

Adaptations for Water

Many structures in fish are adaptations for their aquatic lifestyle. Several are described below.

Read these passages from the text and answer the questions that follow.

- Fish have gills that allow them to "breathe" oxygen in water. Water enters the mouth, passes over the gills, and exits the body through a special opening. Gills absorb oxygen from the water as it passes over them.
- Fish have a streamlined body. They are typically long and narrow, which reduces water resistance when they swim.
- Most fish have several fins for swimming. They use some of their fins to propel themselves through the water and others to steer the body as they swim.
- Fish have a system of muscles for movement. Muscle contractions ripple through the body in waves from head to tail. The contractions whip the tail fin against the water to propel the fish through the water.
- Most fish have a **swim bladder**. This is a balloon-like internal organ that contains gas. By changing the amount of gas in the bladder, a fish can move up or down through the water column.

Fish Organ Systems

Fish have a circulatory system with a two-chambered heart. Their digestive system is complete and includes several organs and glands. Jawed fish use their jaws and teeth to grind up food before passing it to the rest of the digestive tract. This allows them to consume larger prey.

Fish also have a centralized nervous system with a brain. Fish brains are small compared with the brains of other vertebrates, but they are large and complex compared with the brains of invertebrates. Fish also have highly developed sense organs that allow them to see, hear, feel, smell, and taste. Sharks and some other fish can even sense the very low levels of electricity emitted by other animals. This helps them locate prey.

Ouestions

5. Describe the senses of fish.

Lesson 19.2: Multiple Choice

Name_____ Class____ Date____

Circle the letter of the correct choice.

- a. Adaptations for water in fish include
 - a. several fins for swimming.
 - b. a system of muscles for movement.
 - c. gills that allow them to "breathe" oxygen in water.
 - d. all of the above.
- b. A swim bladder allows fish to
 - a. move the tail fin against the water to propel the fish through the water.
 - b. move up or down through water.
 - c. reduce water resistance when they swim.
 - d. get rid of waste products while they swim.

- c. Most fish species belong to which class?
 - a. cartilaginous fish
 - b. lobe-finned fish
 - c. ray-fined fish
 - d. lampreys
- d. Characteristics of sharks include
 - a. an endoskeleton composed of cartilage.
 - b. a swim bladder, like all other fish.
 - c. a relatively small brain.
 - d. all of the above.
- e. Lampreys are known for
 - a. secreting large amounts of thick, slimy mucus.
 - b. feeding on the blood of other fish species using their large round sucker.
 - c. their relatively large brain.
 - d. a lung-like organ for breathing air.
- f. A fish larvae
 - a. is very similar to the adult fish.
 - b. is born sexually mature.
 - c. is attached to a large yolk sac, which provides the larva with food.
 - d. none of the above
- g. Spawning is when a
 - a. large group of adults release their gametes into the water at the same time.
 - b. male and female fish release their gametes together.
 - c. male fertilizes the females eggs.
 - d. a group of eggs develops into larvae.
- h. Fish organ systems include
 - a. a centralized nervous system with a brain.
 - b. an incomplete digestive system with just one opening.
 - c. a circulatory system with a four-chambered heart.
 - d. all of the above.

Lesson 19.3:	Critical Reading		
Name	Class	Date	

Amphibian Reproduction and Development

Read these passages from the text and answer the questions that follow.

Amphibians reproduce sexually with either external or internal fertilization. They attract mates in a variety of ways. For example, the loud croaking of frogs is their mating call. Each frog species has its own distinctive call that other members of the species recognize as their own. Most salamanders use their sense of smell to find a mate. The males produce a chemical odor that attracts females of the species.

Amphibian Eggs

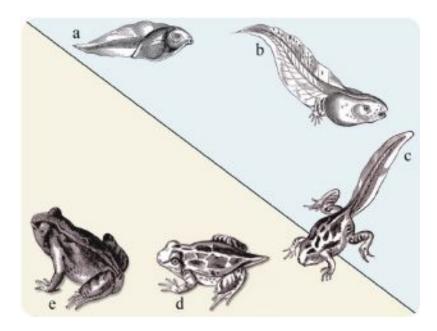

Unlike other tetrapod vertebrates (reptiles, birds, and mammals), amphibians do not produce amniotic eggs. There-

fore, they must lay their eggs in water so they won't dry out. Their eggs are usually covered in a jelly-like substance. The "jelly" helps keep the eggs moist and offers some protection from predators.

Amphibians generally lay large numbers of eggs. Often, many adults lay eggs in the same place at the same time. This helps to ensure that eggs will be fertilized and at least some of the embryos will survive. Once eggs have been laid, most amphibians are done with their parenting.

Amphibian Larvae

The majority of amphibian species go through a larval stage that is very different from the adult form, as you can see from the frog in the diagram below. The early larval, or tadpole, stage resembles a fish. It lacks legs and has a long tail, which it uses to swim. The tadpole also has gills to absorb oxygen from water. As the larva undergoes metamorphosis, it grows legs, loses its tail, and develops lungs. These changes prepare it for life on land as an adult frog.

Frog Development: From Tadpole to Adult. A frog larva (tadpole) goes through many changes by adulthood. How do these changes prepare it for life as an adult frog? (Frog illustrations illustrated by Meyers Konversations-Lexikon, colored and arranged by TomCatX, and under the public domain.)

Questions

1. What are two ways amphibians attract mates?

3. Why do many amphibians lay their eggs together?

4. Describe the amphibian tadpole.

5. Compare the adult frog to the tadpole.

Lesson 19.4:	Critical Reading	
Name	Class	Date
Read these passage	es from the text and answer	r the questions that follow.

Structure and Function in Reptiles

Reptiles have several adaptations for living on dry land that amphibians lack. For example, the skin of most reptiles is covered with scales. The scales are made of very tough keratin, and they protect reptiles from injury and also prevent them from losing water.

Reptile Respiration

The scales of reptiles prevent them from absorbing oxygen through their skin, as amphibians can. Instead, reptiles breathe air only through their lungs. However, their lungs are more efficient than the lungs of amphibians, with more surface area for gas exchange. This is another important reptile adaptation for life on land.

Reptiles have various ways of moving air into and out of their lungs. Lizards and snakes use muscles of the chest wall for this purpose. These are the same muscles used for running, so lizards have to hold their breath when they run. Crocodiles and alligators have a large sheet of muscle below the lungs, called a **diaphragm**, that controls their breathing. This is a structure found also in mammals.

Ectothermy in Reptiles

Like amphibians, reptiles are ectotherms with a slow metabolic rate. Their metabolism doesn't generate enough energy to keep their body temperature stable. Instead, reptiles regulate their body temperature through their behavior. For example, the crocodile in the figure below is soaking up heat from the environment by basking in the sun. Because of their ectothermy, reptiles can get by with as little as one tenth the food needed by endotherms, such as mammals. Some species of reptiles can go several weeks between meals.

Convection by wind

Heat Transfer to an Ectothermic Reptile. This crocodile is being warmed by the environment in three ways. Heat is radiating directly from the sun to the animal's back. Heat is also being conducted to the animal from the rocks it rests on. In addition, convection currents are carrying warm air from surrounding rocks to the animal's body. (*Image courtesy of wildxplorer and under the Creative Commons license CC-BY 2.0. Text added by CK-12 Foundation.*)

Other Reptile Structures

Like amphibians, most reptiles have a heart with three chambers, although crocodiles and alligators have a four-chambered heart like birds and mammals. The reptile brain is also similar in size to the amphibian brain, taking into account overall body size. However, the parts of the reptile brain that control the senses and learned behavior are larger than in amphibians.

Most reptiles have good eyesight and a keen sense of smell. Snakes smell scents in the air using their forked tongue. This helps them locate prey. Some snakes have heat-sensing organs on their head that help them find endothermic prey, such as small mammals and birds.

Questions

1. Describe the skin of reptiles.

2. How do reptiles breathe?

3. "Reptiles are ectotherms." What does this mean?

4. How can reptiles heat their bodies?

5. Describe reptilian senses.

Structure and Function in Birds

Birds can vary considerably in size. The tiny bee hummingbird is just 5 centimeters (2 inches) long, whereas the ostrich towers over people at a height of 2.7 meters (9 feet). All modern birds have wings, feathers, and beaks. They have a number of other unique traits as well, most of which are adaptations for flight. Flight is used by birds as a means of locomotion in order to find food and mates and to avoid predators. Although not all modern birds can fly, they all evolved from ancestors that could.

Wings and Feathers

Wings are an obvious adaptation for flight. They are actually modified front legs. Birds move their wings using

muscles in the chest. These muscles are quite large, making up as much as 35 percent of a bird's body weight.

Feathers help birds fly and also provide insulation and serve other purposes. Birds actually have two basic types of feathers: flight feathers and down feathers. Flight feathers are long, stiff, and waterproof. They provide lift and air resistance without adding weight. Down feathers are short and fluffy. They trap air next to a bird's skin for insulation.

Organ Systems Adapted for Flight

Birds need a light-weight body in order to stay aloft. Even so, flying is hard work, and flight muscles need a constant supply of oxygen- and nutrient-rich blood. The organ systems of birds are adapted to meet these needs.

- Birds have light-weight bones that are filled with air. They also lack a jaw, which in many vertebrates is a dense, heavy bone with many teeth. Instead, birds have a light-weight keratin beak without teeth.
- Birds have air sacs that store inhaled air and push it into the lungs like bellows. This keeps the lungs constantly filled with oxygenated air. The lungs also contain millions of tiny passages that create a very large surface area for gas exchange with the blood.
- Birds have a relatively large, four-chambered heart. The heart beats rapidly to keep oxygenated blood flowing to muscles and other tissues. Hummingbirds have the fastest heart rate at up to 1,200 times per minute. That's almost 20 times faster than the human resting heart rate!
- Birds have a sac-like structure called a crop to store and moisten food that is waiting to be digested. They also have an organ called a gizzard that contains swallowed stones. The stones make up for the lack of teeth by grinding food, which can then be digested more quickly. Both structures make it easier for the digestive system to produce a steady supply of nutrients from food.

Read these passas	ges from the text and answer	the questions that follow.

Characteristics of Mammals

Two characteristics are used to define the mammal class. They are mammary glands and body hair (or fur).

a. Female mammals have **mammary glands**. The glands produce milk after the birth of offspring. Milk is a nutritious fluid. It contains disease-fighting molecules as well as all the nutrients a baby mammal needs. Producing milk for an offspring is called **lactation**.

20.1. Mammalian Traits www.ck12.org

b. Mammals have hair or fur. It insulates the body to help conserve body heat. It can also be used for sensing and communicating. For example, cats use their whiskers to sense their surroundings. They also raise their fur to look larger and more threatening.

Most mammals share several other traits. The traits in the following list are typical of, but not necessarily unique to, mammals.

- The skin of many mammals is covered with sweat glands. The glands produce sweat, the salty fluid that helps cool the body.
- Mammalian lungs have millions of tiny air sacs called **alveoli**. They provide a very large surface area for gas exchange.
- The heart of a mammal consists of four chambers. This makes it more efficient and powerful for delivering oxygenated blood to tissues.
- The brain of a mammal is relatively large and has a covering called the **neocortex**. This structure plays an important role in many complex brain functions.
- The mammalian middle ear has three tiny bones that carry sound vibrations from the outer to inner ear. The bones give mammals exceptionally good hearing. In other vertebrates, the three bones are part of the jaw and not involved in hearing.
- Mammals have four different types of teeth. The teeth of other vertebrates, in contrast, are all alike.

- b. Two characteristics used to define mammals include
 - a. mammary glands and scales.
 - b. mammary glands and hair or fur.
 - c. mammary glands and sweat glands.
 - d. sweat glands and a four-chamber heart.

20.1. Mammalian Traits www.ck12.org

- c. Mammals generate heat by
 - a. keeping a high metabolic rate.
 - b. laying in the sun and absorbing heat.
 - c. increasing blood flow to the skin.
 - d. all of the above
- d. Mammals are unique in having
 - a. lungs with alveoli, tiny, sac-like structures where gas exchange occurs.
 - b. kidneys with alveoli, tiny, sac-like structures where blood filtering occurs.
 - c. alveoli, which increase blood flow to the skin allowing excess heat to escape.
 - d. alveoli with extra mitochondria, keeping metabolism high and generating heat.
- e. Mammals with a carnivorous diet include the
 - a. rabbit, mouse, elephant, zebra, and monkey.
 - b. bear, badger, fox, human, and rat.
 - c. aardvark, whale, hyena, dog, dolphin, and mole.
 - d. giraffe, deer, elk, walrus, human, and rat.
- f. Which of the following statements are true of the mammalian brain? (1) Of all vertebrates, mammals have the biggest and most complex brain for their body size. (2) The cerebrum controls functions such as memory and learning. (3) The larger the neocortex, the greater the mental abilities of an animal. (4) The area of the neocortex is greatest in humans.
 - a. 1 and 2
 - b. 3 and 4
 - c. 1, 2, and 3
 - d. 1, 2, 3, and 4
- g. Mammals are social animals. Which of the following statements is correct?
 - a. Herbivores such as zebras and dolphins live in herds.
 - b. Adults in a herd surround and protect the young, who are most vulnerable to predators.
 - c. Adult males in a pride hunt cooperatively, which is more efficient than hunting alone.
 - d. all of the above
- h. Tree-living mammals have a variety of different specializations for moving in trees, including
 - a. very long arms for swinging from tree to tree.
 - b. sticky pads on their arms and legs that help them cling to tree trunks and branches.
 - c. a prehensile tail used for climbing and hanging from branches.
 - d. all of the above.

Lesson 20.1: Critical Writing

Name______ Class_____ Date_____

www.ck12.org

Thoroughly answer the question below. Use appropriate academic vocabulary and clear and complete sentences. Describe three characteristics of mammals.

20.1. Mammalian Traits

Marsupials

Examples of marsupials are pictured below.

20.2 Reproduction in Mammals

Marsupials have a different way of reproducing that reduces the mother's risks. A **marsupial** is a therian mammal in which the embryo is born at an early, immature stage. The embryo completes its development outside the mother's body in a pouch on her belly. Only a minority of therian mammals are marsupials. They live mainly in Australia.

Marsupials. Marsupials include the kangaroo, koala, and opossum. (From left to right, images courtesy of Fir0002/Flagstaffotos and under GNU-FDL 1.2, koala courtesy of David Iliff and under the Creative Commons license CC-BY-SA 3.0, and courtesy of Drcyrus and under the Creative Commons license CC-BY-SA 2.1 Australia. Composite created by CK-12 Foundation.)

The Marsupial Embryo

The marsupial embryo is nourished inside the uterus with food from a yolk sac instead of through a placenta. The yolk sac stores enough food for the short period of time the embryo remains in the uterus. After the embryo is born, it moves into the mother's pouch, where it clings to a nipple. It remains inside the pouch for several months while it continues to grow and develop. Even after the offspring is big enough to leave the pouch, it may often return to the pouch for warmth and nourishment. Eventually, the offspring is mature enough to remain outside the pouch on its own.

Pros and Cons of Marsupial Reproduction

In marsupials, the short period of development within the mother's uterus reduces the risk of her immune system attacking the embryo. In addition, the marsupial mother doesn't have to eat extra food or carry a large fetus inside her. The risks of giving birth to a large fetus are also avoided. Another pro is that the mother can expel the embryo from her pouch if she is pursued by a predator or if food is scarce. On the other hand, a newborn marsupial is tiny and fragile. Therefore, it may be less likely to survive than a newborn placental mammal.

Questions

1. What is a marsupial? Give an example.

_			.4					
3.	How	1S	the	marsupi	ial emb	rvo	nourished	17

4. Describe an advantage of marsupial development.

5. Describe a disadvantage of marsupial development.

Lesson 20.2: Multiple Choice

Name_____ Class____ Date____

Circle the letter of the correct choice.

a. Therian mammals

- a. are viviparous.
- b. have young that are born live.
- c. have young that are born either as relatively large, well-developed fetuses or as tiny, immature embryos.
- d. all of the above

b. All female mammals have

- a. ovaries, which are the organs that produce eggs.
- b. a uterus, which is a tubular passageway through which the embryo or fetus leaves the mother's body during birth.
- c. a vagina, a pouch-like, muscular organ where the embryo or fetus develops until birth.
- d. all of the above.

c. Which statement is true of a placenta?

- a. The placenta passes oxygen, nutrients, and other useful substances from the fetus to the mother.
- b. The placenta passes oxygen, nutrients, and other useful substances from the mother to the fetus.
- c. The placenta mixes blood from the mother and fetus together.
- d. The placenta protects the mother from being attacked by the fetal immune system.

d. Advantages to placental reproduction include

- a. reduced mobility of the mother as the baby grows.
- b. the ability to abandon the baby to save the mother's life if necessary.
- c. a long period of fetal growth, allowing the fetus to become large and mature before birth.
- d. all of the above.

e. Marsupials include

- a. the kangaroo.
- b. the platypus.
- c. humans.
- d. all whales.

f. Among mammals, female monotremes are unique in that they

- a. have a pouch where the fetus completes development.
- b. have a cloaca with one opening.
- c. "sweat" milk from a patch on their mammary glands.
- d. live mainly in Australia.

g. Female monotremes

- a. lay eggs.
- b. have a placenta.
- c. lack a vagina but have a uterus.
- d. lay eggs and have a placenta.

h. An advantage to marsupial reproduction is that

- a. the marsupial mother has to eat extra food, and marsupials love to eat.
- b. there is a short period of development within the mother's uterus.
- c. a newborn marsupial is small, making delivery and development easy on the mother.

Date_

d. due to their size, newborn marsupials have a very high survival rate.

Lesson 20.2:	vocabulary i

13.	. Whales are mammals	, but seals are not.	
14.	. Humans and rats are §	grouped into the sar	me superorder.
15.	. Though not mammals	, cynodonts evolve	ed many mammalian traits.
Lessor	n 20.3: Critical Re	eading	
Name	C	lass	Date
Read thes	se passages from the tex	at and answer the g	questions that follow.

Evolution of Early Mammals

The earliest mammals evolved from cynodonts. But the evolution of mammals didn't end there. Mammals continued to evolve. Monotreme mammals probably split off from other mammals first. They were followed by marsupials. Placental mammals probably evolved last.

Evolution of Monotremes

The first monotremes may have evolved about 150 million years ago. Early monotreme fossils have been found in Australia. An example is a genus called *Steropodon*. It may have been the ancestor of the platypus. Early

monotremes retained some of the traits of their therapsid ancestors. For example, they laid eggs and had a cloaca. These traits are still found in modern monotremes.

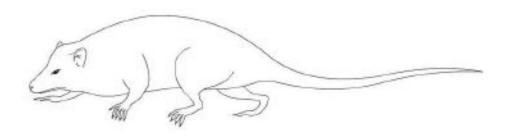

Evolution of Marsupials

The first marsupials may have evolved about 130 million years ago. One of the earliest was the extinct genus *Sinodelphys*. A fossil of this mammal is shown in the FlexBook. It is a remarkable fossil find. It represents a nearly complete animal. Even tufts of hair and imprints of soft tissues were preserved.

Sinodelphys was about 15 centimeters (6 inches) long. Its limb structure suggests that it was a climbing animal. It could escape from predators by climbing into trees. It probably lived on a diet of insects and worms.

Evolution of Placental Mammals

The earliest placental mammals may have evolved about 110 million years ago. The ancestor of placental mammals may be the extinct genus *Eomaia*. Fossils of *Eomaia* have been found in what is now China. It was only about 10 centimeters (4 inches) long. It was a tree climber and probably ate insects and worms. *Eomaia* had several traits of placental mammals. The illustration below shows how *Eomaia* may have looked.

Probable Ancestor of Placental Mammals: Eomaia. Eomaia lived a little over 100 million years ago. (*Image courtesy of Mateus Zica and under the Creative Commons license CC-BY-SA 3.0.*)

The placental mammal descendants of *Eomaia* were generally more successful than marsupials and monotremes. On most continents, placental mammals became the dominant mammals, while marsupials and monotremes died out. Marsupials remained the most common and diverse mammals only in Australia. The debate over the reasons for their success there is not yet resolved.

Questions

1. Describe an early monotreme mammal.

3	Describe an	early	nlacental	mammal

4. What is the order of evolution of the three types of mammals? How long ago did they evolve?

5. Which type of mammals became the most successful?

Lesson 20.3: Multiple Choice

Name_____ Class____ Date____

Circle the letter of the correct choice.

- a. When did the earliest mammal live?
 - a. over 150 million years ago
 - b. 150 million years ago
 - c. 130 million years ago
 - d. 110 million years ago
- b. Pelycosaurs
 - a. had sprawling legs and walked like a lizard.
 - b. had teeth of different types.
 - c. was a synapsid.
 - d. all of the above
- c. Therapsids
 - a. had a good sense of hearing.
 - b. had the ability to regulate their body temperature.
 - c. had legs positioned under the body instead of along the sides.
 - d. all of the above
- d. By the end of the Triassic Period, cynodonts had
 - a. three tiny bones in the middle ear.
 - b. ectothermy.
 - c. a diaphragm for eating.
 - d. all of the above.
- e. Place the following in their correct evolutionary order.
 - a. marsupials placental mammals monotremes
 - b. monotremes marsupials placental mammals
 - c. marsupials monotremes placental mammals
 - d. placental mammals marsupials monotremes
- f. The most widely accepted traditional classification of mammals divides living placental mammals into ______ orders.
 - a. 7
 - b. 12
 - c. 17
 - d. 22
- g. Traits of primates include
 - a. five digits on their hands and feet.
 - b. rubbery pads on their feet.
 - c. long, pointed canine teeth.
 - d. all of the above.
- h. The most successful mammals are the
 - a. marsupials, who practically have a whole continent to themselves.
 - b. monotremes, who have a very specific niche without competitors.
 - c. placental mammals, who have become dominant on most continents.
 - d. none of the above

Evolution of Animal Behavior

To the extent that behaviors are controlled by genes, they may evolve through natural selection. If behaviors increase fitness, they are likely to become more common over time. If they decrease fitness, they are likely to become less common.

Nature vs. Nurture

Some behaviors seem to be controlled solely by genes. Others appear to be due to experiences in a given environment. Whether behaviors are controlled mainly by genes or by the environment is often a matter of debate. This is

called the **nature-nurture debate**. Nature refers to the genes an animal inherits. Nurture refers to the environment that the animal experiences. In reality, most animal behaviors are not controlled by nature or nurture alone. Instead, they are influenced by both nature and nurture. In dogs, for example, the tendency to behave toward other dogs in a certain way is probably controlled by genes. However, the normal behaviors can't develop in an environment that lacks other dogs. A puppy raised in isolation from other dogs may never develop the normal behaviors. It may always fear other dogs or act aggressively toward them.

How Behaviors Evolve

It's easy to see how many common types of behavior evolve. That's because they obviously increase the fitness of the animal performing them. For example, when wolves hunt together in a pack, they are more likely to catch prey (see the figure below). Therefore, hunting with others increases a wolf's fitness. The wolf is more likely to survive and pass its genes to the next generation by behaving this way.

(Image courtesy of Doug Smith and the U.S. National Park Service and under the public domain.)

The evolution of certain other types of behavior is not as easy to explain. An example is a squirrel chattering loudly to warn other squirrels that a predator is near. This is likely to help the other squirrels avoid the predator. Therefore, it could increase their fitness. But what about the squirrel that raises the alarm? This squirrel is more likely to be noticed by the predator. Therefore, the behavior may actually lower this squirrel's fitness. How could such a behavior evolve through natural selection?

One possible answer is that helping others often means helping close relatives. Close relatives share many of the same genes that they inherited from their common ancestor. As a result, helping a close relative may actually increase the chances that copies of one's own genes will be passed to the next generation. In this way, a behavior that puts oneself at risk could actually increase through natural selection. This form of natural selection is called kin selection.

Questions

1. Is behavior controlled by genes? If a behavior is controlled by a gene, does that behavior evolve?

_	** **						-
7	What	10	the	nature.	-nurture	dehate	٠,

3. How do many common types of behavior evolve in animals? Give an example.

4. "Helping others often means helping close relatives." What does this statement refer to?

5. What is "kin selection"?

21.1 Organization of the Human Body

Lesson 21.1: Tru		
		Date
Write true if the staten	nent is true or false if th	he statement is false.
1. Cells are the	basic units of structure	e and function in the human body.
2. The human b	ody consists of four tis	ssue types.
3. Bone is an ex	cample of epithelial tiss	sue.
4. Epithelial tis	sue is made up of cells	that only line outer body surfaces.
5. Muscles attac	ched to bones enable th	ne body to move.
6. Neurons car	ry electrical messages.	
7. After tissues.	organs are the next lev	vel of organization of the human body.
8. An organ is a	structure that consists	s of only two types of tissues that work together to do the same job.
9. The digestive	e system breaks down f	food and absorbs its nutrients.
10. The endocr	ne system removes exc	cess fluid from tissues and transports substances.
11. All of the o	rgans and organ system	ns of the human body work together like a well-oiled machine.
12. The nervou	s system controls virtua	ally all body activities.
13. Keeping a s	table internal environm	nent does not require constant adjustments.
14. A low conc	entration of carbon dio	oxide in the blood triggers faster breathing.
15. A low level	of water in the blood to	riggers retention of water by the kidneys.
Lesson 21.1: Cr		
Name	Class	Date

Maintaining Homeostasis

The process in which organ systems work to maintain a stable internal environment is called homeostasis. Keeping a stable internal environment requires constant adjustments. Here are just three of the many ways that human organ systems help the body maintain homeostasis:

- Respiratory system: A high concentration of carbon dioxide in the blood triggers faster breathing. The lungs exhale more frequently, which removes carbon dioxide from the body more quickly.
- Excretory system: A low level of water in the blood triggers retention of water by the kidneys. The kidneys produce more concentrated urine, so less water is lost from the body.

• Endocrine system: A high concentration of sugar in the blood triggers secretion of insulin by an endocrine gland called the pancreas. Insulin is a hormone that helps cells absorb sugar from the blood.

Failure of Homeostasis

Many homeostatic mechanisms such as these work continuously to maintain stable conditions in the human body. Sometimes, however, the mechanisms fail. When they do, cells may not get everything they need, or toxic wastes may accumulate in the body. If homeostasis is not restored, the imbalance may lead to disease or even death.

may accumulate in the body. If homeostasis is not restored, the imbalance may lead to disease or even death.
Questions
1. What is homeostasis?
2. What is the result of the lungs exhaling more frequently?
3. What is the result of a more concentrated urine?
4. What is the function of insulin?

415

5. If there is a failure of homeostasis and homeostasis is not restored, what may happen?

Lesson 21.1: Mu	ıltiple	Choice
-----------------	---------	--------

Name		Date
------	--	------

Circle the letter of the correct choice.

- a. Approximately how many cells does the average person reaching adulthood have?
 - a. 100 thousand
 - b. 100 million
 - c. 100 billion
 - d. 100 trillion
- b. Cartilage is an example of which of the following tissues?
 - a. connective tissue
 - b. epithelial tissue
 - c. muscle tissue
 - d. none of the above
- c. The lymphatic system removes which of the following from tissues?
 - a. excess gases
 - b. excess fluids
 - c. excess solids
 - d. none of the above
- d. All of the organs and organ systems of the human body work well together because they are closely regulated by which of the following systems?
 - a. lymphatic and nervous
 - b. endocrine and muscular
 - c. nervous and endocrine
 - d. circulatory and lymphatic
- e. Which of the following systems secretes hormones?
 - a. nervous
 - b. endocrine
 - c. circulatory
 - d. respiratory
- f. Which of the following systems produces gametes?
 - a. reproductive
 - b. endocrine

- c. circulatory
- d. nervous
- g. Insulin is secreted by an endocrine gland called the
 - a. thyroid.
 - b. pineal body.
 - c. pancreas.
 - d. gall bladder.
- h. The correct order of levels of organization is
 - a. $cell \rightarrow organ \rightarrow tissue \rightarrow organism$.
 - b. $cell \rightarrow tissue \rightarrow organ \rightarrow organ system$.
 - c. organelle \rightarrow cell \rightarrow organ \rightarrow organ system.
 - d. atom \rightarrow cell \rightarrow organ \rightarrow tissue.
- Which of the following statements is true concerning maintaining homeostasis? (1) Homeostasis is maintained through the interactions of a number of organ systems. (2) Not maintaining homeostasis can lead to death.
 (3) A high concentration of carbon dioxide in the blood triggers faster breathing to remove the oxygen. (4) A high level of water in the blood triggers retention of water by the kidneys.
 - a. 1 only
 - b. 1 and 2
 - c. 3 and 4

Lesson 21.1: Vocabulary I

d. All four statements are correct.

Name	Class Date
Match	the vocabulary word with the proper definition.
Defini	itions
	1. a structure that consists of two or more types of tissues that work together to do the same job
	2. made up of neurons, or nerve cells, that carry electrical messages
	3. made up of cells that form the body's structure
	4. a group of connected cells that have a similar function
	5. takes in oxygen and releases waste gases
	6. made up of cells that line body surfaces
	7. secretes hormones that regulate other organs and organ systems
	8. basic units of structure and function in the human body
	9. a hormone that helps cells absorb sugar from the blood
	10. process in which organ systems work to maintain a stable internal environment
	11. made up of cells that have the unique ability to contract, or become shorter
	12. a group of organs that work together to carry out a complex overall function

21.2 The Skeletal System

Lesson 21.2:	True or False		
Name	Class	Date	
Write true if the sta	tement is true or false if th	he statement is false.	
1. Cartilage	is a type of dense connect	tive tissue.	
2. One of the	e functions of the skeleton	n is to produce blood cells.	
3. When blo	od levels of minerals are t	too high, bones release some of the minerals back into the blo	od.
4. The basic	structure of bones is bone	e matrix.	
5. There are	three types of specialized	l cells in human bones.	
6. Osteoclas	ts make new bone cells.		
7. Bones are	dynamic, living tissues.		
8. Compact	bone makes up the dense	outer layer of bone.	
9. Periosteur	m is soft connective tissue	2 .	
10. Early in	the development of a hum	nan fetus, the skeleton is made entirely of bone.	
11. A joint i	s a place where two or mo	ore bones of the skeleton meet.	
12. There ar	e four main types of joints	s.	
13. Immoval	ble joints are also known a	as synovial joints.	
14. Of all the	e movable joints, a ball-an	nd-socket joint has the greatest range of motion.	
15. Despite	their hardness and strength	h, bones can suffer from injury and disease.	
Lesson 21.2:	Critical Reading		
Name	Class	Date	
Read these passage	es from the text and answer	er the auestions that follow.	

Types of Joints

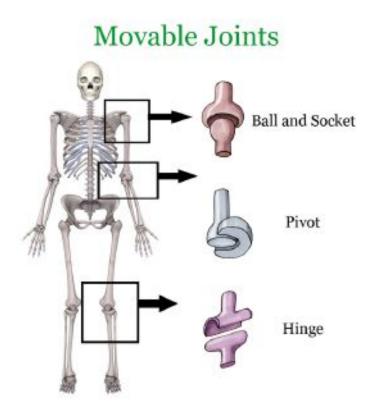

There are three main types of joints: immovable, partly movable, and movable.

- Immovable joints allow no movement because the bones at these joints are held securely together by dense collagen. The bones of the skull are connected by immovable joints.
- Partly movable joints allow only very limited movement. Bones at these joints are held in place by cartilage. The ribs and sternum are connected by partly movable joints.
- Movable joints allow the most movement. Bones at these joints are connected by ligaments. Movable joints are the most common type of joints in the body, so they are described in more detail next.

Movable Joints

Movable joints are also known as synovial joints. This is because the space between the bones is filled with a thick fluid called synovial fluid that cushions the joint.

There are a variety of types of movable joints, which are illustrated below. The joints are classified by how they move. For example, a ball-and-socket joint, such as the shoulder, has the greatest range of motion, allowing movement in several directions. Other movable joints, including hinge joints such as the knee, allow less movement.

Types of Movable Joints in the Human Skeleton. Movable joints can move in a variety of ways. Try moving each of the joints indicated in the diagram. Can you tell how their movements differ? Other joints in the human skeleton that are not depicted here include saddle, elipsoid, and plane joints. (Skeleton image copyright 3drenderings, 2010, used under license from Shutterstock.com. Joints images courtesy of Produnis and under GNU-FDL 1.2. Composite created by CK-12 Foundation.)

Ouestions

1. What are the differences among the three main types of joints?

3. Name three types of movable joints.

4. What are other joints in the human skeleton not depicted in the figure?

5. Try moving each of the joints indicated in the diagram. Can you tell how their movements differ?

Lesson 21.2: Multiple Choice

Name_____ Class____ Date____

Circle the letter of the correct choice.

- a. How many bones does the human skeleton consist of?
 a. 203
 b. 206
 c. 216
 d. 235
- b. Bone matrix consists of tough fibers made of
 - a. carbohydrate.
 - b. fat.
 - c. protein.
 - d. none of the above.
- c. Osteoblasts secrete
 - a. calcium.
 - b. water.
 - c. hormones.
 - d. collagen.
- d. Which of the following makes up the dense outer layer of bone?
 - a. compact bone
 - b. spongy bone
 - c. bone marrow
 - d. periosteum
- e. Which of the following produces blood cells?
 - a. compact bone
 - b. spongy bone
 - c. bone marrow
 - d. periosteum
- f. A person reaches skeletal maturity
 - a. in the early teens.
 - b. in the late teens or early twenties.
 - c. in the mid twenties.
 - d. in the late twenties or early thirties.
- g. The main difference between osteoblasts and osteoclasts is that
 - a. osteoblasts make new bone cells and osteoclasts dissolve bone material.
 - b. osteoclasts make new bone cells and osteoblasts dissolve bone material.
 - c. osteoblasts make new bone from cartilage and osteoclasts make cartilage from bone.
 - d. osteoblasts make new bone cells and osteoclasts regulate bone mineral homeostasis.
- h. The ribs and sternum are connected by
 - a. immovable joints.
 - b. partly moveable joints.
 - c. movable joints.
 - d. none of the above.

Lesson 21.2: Vocabulary I

2. Each muscl	e fiber is a very short, th	nin cell.	
3. There are fo	our types of muscle tissu	nes in the human body.	
4. Both skelet	al and cardiac muscles a	appear striated, or striped.	
5. Contraction	s of smooth muscle are	voluntary.	
6. Skeletal mu	scle is the most common	n type of muscle in the human body.	
7. Cardiac mu	scle contains a great ma	ny mitochondria.	
8. There are w	vell over 600 skeletal mu	iscles in the human body.	
9. Each skelet	al muscle consists of 12.	5 skeletal muscle fibers.	
10. Muscles c	an contract, actively exte	end, and lengthen.	
11. In exercise	es such as weight lifting,	, skeletal muscle contracts against a resisting	g force
12. Continued	exercise is necessary to	maintain bigger, stronger muscles.	
13. Each muse	cle fiber contains hundre	eds of organelles called myofibrils.	
14. The region	between two Z lines is	called a sarcomere.	
15. Voluntary	contractions of cardiac	and smooth muscles are also controlled by r	nerves.
13. Voluntary	contractions of cardiac a	and smooth muscles are also controlled by f	nerve
	vitical Bandina		
Lesson 21.3: C	ritical Heading		
Name	Class	Data	

What Are Muscles?

Muscles are organs composed mainly of muscle cells, which are also called **muscle fibers**. Each muscle fiber is a very long, thin cell that can do something no other cell can do. It can contract, or shorten. Muscle contractions are responsible for virtually all the movements of the body, both inside and out. There are three types of muscle tissues in the human body: cardiac, smooth, and skeletal muscle tissues. They are shown and described below.

Types of Muscle Tissue. Both skeletal and cardiac muscles appear striated, or striped, because their cells are arranged in bundles. Smooth muscles are not striated because their cells are arranged in sheets instead of bundles. (From left to right, images courtesy of the Department of Histology at Jagiellonian University Medical College, Polarlys, and Nathanael Reveal (Nathanael). All images under GNU-FDL 1.2.)

Smooth Muscle

Muscle tissue in the walls of internal organs such as the stomach and intestines is **smooth muscle**. When smooth muscle contracts, it helps the organs carry out their functions. For example, when smooth muscle in the stomach contracts, it squeezes the food inside the stomach, which helps break the food into smaller pieces. Contractions of smooth muscle are involuntary. This means they are not under conscious control.

Skeletal Muscle

Muscle tissue that is attached to bone is **skeletal muscle**. Whether you are blinking your eyes or running a marathon, you are using skeletal muscle. Contractions of skeletal muscle are voluntary, or under conscious control. Skeletal muscle is the most common type of muscle in the human body, so it is described in more detail below.

Cardiac Muscle

Cardiac muscle is found only in the walls of the heart. When cardiac muscle contracts, the heart beats and pumps blood. Cardiac muscle contains a great many mitochondria, which produce ATP for energy. This helps the heart resist fatigue. Contractions of cardiac muscle are involuntary, like those of smooth muscle.

Questions

1. Describe what a muscle fiber looks like and what it can do.

2. What are the three types of muscle tissues in the human body and where are they located?

3. Explain how cell arrangement	ent causes a muscle to a	appear either striated or not striated.
4 F 1 4	1'-4 b db '4 '	1
4. For each type of muscle tis	sue, list whether it is vo	luntary or involuntary.
5. Why is it important for card	diac muscle to have man	ny mitochondria?
Lesson 21.3: Multiple	Choice	
Name	Class	_ Date

Circle the letter of the correct choice.

- a. Smooth muscle is found in the
 - a. heart.
 - b. stomach.
 - c. upper leg.
 - d. middle ear.
- b. Skeletal muscle fibers are wrapped in
 - a. fat.
 - b. bone.
 - c. connective tissue.

- d. none of the above.
- c. Skeletal muscles need a rich blood supply to provide them with
 - a. oxygen.
 - b. carbon dioxide.
 - c. water.
 - d. none of the above.
- d. The biceps and triceps muscles are located in the
 - a. lower arm.
 - b. upper arm.
 - c. knee.
 - d. stomach.
- e. Each myofibril is made up of how many types of protein filaments?
 - a. one
 - b. two
 - c. three
 - d. four
- f. Actin filaments are anchored to structures called
 - a. W lines.
 - b. X lines.
 - c. Y lines.
 - d. Z lines.
- g. Muscles need a stimulus from which of the following to "tell" them to contract?
 - a. a muscle cell
 - b. the skeleton
 - c. a nerve cell
 - d. none of the above
- h. Two main proteins found in muscle are

Class

- a. smooth and skeletal.
- b. tendons and ligaments.
- c. actin and myosin.
- d. myofibrils and fibers.

Lesson 21.3: Vocabulary I

Match the vocabulary word with the proper definition.
Definitions
1. muscle tissue that is attached to bone
2. long, thin muscle cell that has the ability to contract, or shorten
3. theory that explains muscle contraction by the sliding of myosin filaments over actin filaments within muscle fibers
4. tough connective tissue that attaches skeletal muscle to bones of the skeleton
5. human body system that includes all the muscles of the body

Date

Name

12. Within a sarcomere, myosin filaments ______ the actin filaments.

Functions of the Skin

The skin has multiple roles in the body. Many of these roles are related to homeostasis. The skin's main functions are preventing water loss from the body and serving as a barrier to the entry of microorganisms. In addition, melanin in the skin blocks UV light and protects deeper layers from its damaging effects.

Read these passages from the text and answer the questions that follow.

The skin also helps regulate body temperature. When the body is too warm, sweat is released by the sweat glands and spreads over the skin surface. As the sweat evaporates, it cools the body. Blood vessels in the skin also dilate, or widen, when the body is too warm. This allows more blood to flow through the skin, bringing body heat to the surface, where it radiates into the environment. When the body is too cool, sweat glands stop producing sweat, and blood vessels in the skin constrict, or narrow, thus conserving body heat.

Questions

1. What are the skin's two main functions?

2. What is the function of melanin in the skin?

3. How does sweat regulate body temperature when the body is too warm?

4. How do blood vessels in the skin regulate body temperature when the body is too cool?

13. The cere	ebrum is the largest part of	the brain.	
14. The reas	on you can smell your foo	od is because of the taste buds in your nose.	
15. Dendrite	es extend from the cell bod	ly and send nerve impulses to other neurons.	
Lesson 22.1:	Critical Reading		
Name	Class	Date	
Read these passage	es from the text and answer	r the questions that follow.	

Nerve Cells

Although the nervous system is very complex, nervous tissue consists of just two basic types of nerve cells: neurons and glial cells. **Neurons** are the structural and functional units of the nervous system. They transmit electrical signals, called **nerve impulses**. Glial cells provide support for neurons. For example, they provide neurons with nutrients and other materials.

Neuron Structure

As shown in the FlexBook, a neuron consists of three basic parts: the cell body, dendrites, and axon. You can watch an animation of the parts of a neuron at this link: http://www.garyfisk.com/anim/neuronparts.swf.

- The **cell body** contains the nucleus and other cell organelles.
- Dendrites extend from the cell body and receive nerve impulses from other neurons.
- The **axon** is a long extension of the cell body that transmits nerve impulses to other cells. The axon branches at the end, forming axon terminals. These are the points where the neuron communicates with other cells.

Myelin Sheath

The axon of many neurons has an outer layer called a **myelin sheath**. Myelin is a lipid produced by a type of a glial cell known as a Schwann cell. The myelin sheath acts like a layer of insulation, similar to the plastic that encases an electrical cord. Regularly spaced nodes, or gaps, in the myelin sheath allow nerve impulses to skip along the axon very rapidly.

Types of Neurons

Neurons are classified based on the direction in which they carry nerve impulses.

- Sensory neurons carry nerve impulses from tissues and organs to the spinal cord and brain.
- Motor neurons carry nerve impulses from the brain and spinal cord to muscles and glands.

• Interneurons carry nerve impulses back and forth between sensory and motor neurons.
Questions
1. What is a neuron? What are glial cells?
2. What is the role of a dendrite and an axon?

3. What does the myelin sheath do?

4. Describe the three types of neurons.

Circle the letter of the correct choice.

- a. Neurons transmit electrical signals called
 - a. nerve signals.
 - b. nerve impulses.
 - c. nerve potential.
 - d. axon impulses.
- b. The parts of a neuron include
 - a. the cell body.
 - b. one axon.
 - c. numerous dendrites.
 - d. all of the above.
- c. What is an action potential?
 - a. An action potential is a sudden reversal of the electrical charge across the membrane of a resting neuron.
 - b. An action potential is a sudden reversal of the electrical charge across the membrane of an active neuron.
 - c. An action potential is a slow reversal of the electrical charge across the membrane of a resting neuron.
 - d. An action potential is a sudden reversal of the chemical charge across the membrane of a resting neuron.
- d. At the synapse,
 - a. neurotransmitter molecules travel across the axon terminals and bind to receptors on the membrane of the other cell.
 - b. neurotransmitter molecules travel across the axon terminals and bind to vesicles on the membrane of the other cell.
 - c. neurotransmitter molecules travel across the synaptic cleft and bind to receptors on the membrane of the other cell.
 - d. neurotransmitter molecules travel across the synaptic cleft and bind to signal proteins on the membrane of the other cell.
- e. The largest part of the human brain is the
 - a. cerebellum.
 - b. cerebrum.
 - c. frontal lobe.
 - d. brain stem.

- f. Your somatic nervous system is responsible for
 - a. involuntary activities not under conscious control.
 - b. emergency situations.
 - c. the organs of your digestive system.
 - d. voluntary activities that are under conscious control.
- g. Alzheimer's disease most likely occurs when
 - a. nervous tissue degenerates.
 - b. nervous tissue may become infected by microorganisms.
 - c. there are problems with blood flow.
 - d. there are brain or spinal cord injuries.
- h. Your sense of balance is the responsibility of
 - a. your eyes.
 - b. your ears.
 - c. both your eyes and ears.
 - d. your sense of touch.
- i. The peripheral nervous system consists of
 - a. all the nervous tissue that lies outside the central nervous system.
 - b. your brain and spinal cord.
 - c. all your neurons and axons.
 - d. all of the above.
- j. The central nervous system consists of
 - a. all the nervous tissue that lies outside the central nervous system.
 - b. just your brain.
 - c. just your spinal cord.
 - d. your brain and spinal cord.

Thoroughly answer	the question below. Use a	appropriate academic vocabulary and clear and complete sentences.
An action potential	can be referred to as a "	wave of depolarization" down the axon. Explain what you think th

means.

22.2 The Endocrine System

	Class	Date
Write true if the	statement is true or false if th	e statement is false.
1. Steroid	l hormones can enter the nucle	eus and influence the expression of genes.
2. Hormo	ones are chemical messengers.	
3. A targe	et cell is the type of cell that h	as an effect on hormones.
4. Non-st	eroid hormones bind to their i	receptors in the cytoplasm of the cell.
5. The pa	ncreas is a large endocrine gla	and in the neck.
6. Hypers	secretion by an endocrine glar	nd is often caused by a tumor.
7. Most h	ormone feedback mechanism	s involve positive feedback loops.
8. Milk p	roduction by a mother for her	baby is positively regulated.
9. Type 2	diabetes cannot be treated by	insulin injections.
10. The t	hyroid gland is often called th	e "master gland" of the endocrine system.
11. Secon	ndary messengers affect cell p	rocesses inside the cell.
12. Nega	tive feedback controls insulin	secretion by the adrenal gland.
13. Nega	tive feedback regulation occur	rs when a product feeds back to decrease its own production
14 Endo	crine hormones travel through	nout the body in the blood.

Hormone Regulation: Feedback Mechanisms

Hormones control many cell activities, so they are very important for homeostasis. But what controls the hormones themselves? Most hormones are regulated by feedback mechanisms. A feedback mechanism is a loop in which a product feeds back to control its own production. Most hormone feedback mechanisms involve negative feedback loops. Negative feedback keeps the concentration of a hormone within a narrow range.

Negative Feedback

Negative feedback occurs when a product feeds back to decrease its own production. This type of feedback brings things back to normal whenever they start to become too extreme. The thyroid gland is a good example of this type of regulation. It is controlled by the negative feedback loop shown in the FlexBook.

Here's how thyroid regulation works. The hypothalamus secretes thyrotropin-releasing hormone, or TRH. TRH stimulates the pituitary gland to produce thyroid-stimulating hormone, or TSH. TSH, in turn, stimulates the thyroid gland to secrete its hormones. When the level of thyroid hormones is high enough, the hormones feed back to stop the hypothalamus from secreting TRH and the pituitary from secreting TSH. Without the stimulation of TSH, the thyroid gland stops secreting its hormones. Soon, the level of thyroid hormone starts to fall too low. What do you think happens next? Negative feedback also controls insulin secretion by the pancreas.

Positive feedback

Positive feedback occurs when a product feeds back to increase its own production. This causes conditions to become increasingly extreme. An example of positive feedback is milk production by a mother for her baby. As the baby suckles, nerve messages from the nipple cause the pituitary gland to secrete prolactin. Prolactin, in turn, stimulates the mammary glands to produce milk, so the baby suckles more. This causes more prolactin to be secreted and more milk to be produced. This example is one of the few positive feedback mechanisms in the human body. What do you think would happen if milk production by the mammary glands was controlled by negative feedback instead?

Circle the letter of the correct choice.

- a. Glands of the endocrine system include
 - a. the thyroid gland.
 - b. the pituitary gland.
 - c. the gonads.
 - d. all of the above.
- b. Negative feedback regulation of hormones occurs
 - a. when a reactant feeds back to decrease its own production.
 - b. when a product feeds back to increase its own production.
 - c. when a product feeds back to decrease its own production.
 - d. when a reactant feeds back to increase its own production.
- c. Which statement is true about the thyroid hormones? (1) They increase the rate of metabolism in cells throughout the body. (2)They control how quickly cells use energy. (3) They are not steroid hormones. (4) They are released by the parathyroid glands.
 - a. 1 only
 - b. 1 and 2
 - c. 1, 2, and 3
 - d. 1, 2, 3, and 4
- d. Steroid hormones
 - a. can influence gene expression.

- b. can diffuse across the plasma membrane.
- c. are made of lipids.
- d. all of the above
- e. Milk production
 - a. is negatively regulated by prolactin.
 - b. is positively regulated by prolactin.
 - c. is positively regulated by milk-producing factor.
 - d. is an unregulated process in new mothers.
- f. Thyrotropin-releasing hormone, or TRH,
 - a. is regulated through a negative feedback mechanism.
 - b. is regulated through a positive feedback mechanism.
 - c. is not regulated.
 - d. none of the above
- g. The hormones released by the pancreas
 - a. are located near the thyroid gland.
 - b. include insulin and glucose.
 - c. work together to control the level of glucose in the blood.
 - d. all of the above
- h. Which of the following statements is true concerning the hypothalamus? (1) The hypothalamus is actually part of the brain. (2) The hypothalamus can be considered a link between the nervous and endocrine systems. (3) The hypothalamus releases anti-diuretic hormone. (4) The hypothalamus produces hormones that directly regulate other body processes.
 - a. 1 only
 - b. 1 and 2
 - c. 1, 2, and 3
 - d. 1, 2, 3, and 4

14. Platelets re	elease chemicals that are	needed for blood clotting.
15. Diseases o	f the heart and blood ve	ssels are very common.
Lesson 23.1: C	ritical Reading	
Name	Class	Date

The heart is a muscular organ in the chest. It consists mainly of cardiac muscle tissue and pumps blood through blood vessels by repeated, rhythmic contractions. The heart has four chambers, as illustrated below: two upper atria (singular, atrium) and two lower ventricles. Valves between chambers keep blood flowing through the heart in just

The Heart

one direction.

The chambers of the heart and the valves between them are shown here. (*Image courtesy of Wapcaplet and Yaddah and under GNU-FDL 1.2.*)

Blood Flow Through the Heart

Blood flows through the heart in two separate loops, which are indicated by the arrows in the figure above.

- a. Blood from the body enters the right atrium of the heart. The right atrium pumps the blood to the right ventricle, which pumps it to the lungs. This loop is represented by the blue arrows in the figure above.
- b. Blood from the lungs enters the left atrium of the heart. The left atrium pumps the blood to the left ventricle, which pumps it to the body. This loop is represented by the red arrows in the figure above.

Heartbeat

Unlike skeletal muscle, cardiac muscle contracts without stimulation by the nervous system. Instead, specialized cardiac muscle cells send out electrical impulses that stimulate the contractions. As a result, the atria and ventricles normally contract with just the right timing to keep blood pumping efficiently through the heart.

Questions

1. What is the role of the heart?

2. T	ne	chambers of the heart are:	 ,	,	,

3. What is the main difference between the right side and left side of the heart?

4. What causes the heart to beat? Describe how this occurs.

Lesson 23.1: Multiple Choice

Name Class Date

Circle the letter of the correct choice.

- a. The materials carried by the circulatory system include which of the following? (1) blood, (2) hormones, (3) oxygen, (4) cellular wastes.
 - a. 1 only
 - b. 1 and 2
 - c. 1, 2, and 3
 - d. 1, 2, 3, and 4
- b. The correct order of blood flow is
 - a. $aorta \rightarrow right \ atrium \rightarrow right \ ventricle \rightarrow lungs \rightarrow left \ atrium \rightarrow left \ ventricle \rightarrow vena \ cava.$
 - b. vena cava \rightarrow right atrium \rightarrow right ventricle \rightarrow lungs \rightarrow left atrium \rightarrow left ventricle \rightarrow aorta.
 - c. vena cava \rightarrow left atrium \rightarrow left ventricle \rightarrow lungs \rightarrow right atrium \rightarrow right ventricle \rightarrow aorta.
 - d. $aorta \rightarrow left \ atrium \rightarrow left \ ventricle \rightarrow lungs \rightarrow right \ atrium \rightarrow right \ ventricle \rightarrow vena \ cava.$
- c. The major blood vessels include
 - a. arteries.

- b. veins.
- c. capillaries.
- d. all of the above.

d. Which statement is correct?

- a. The pulmonary circulation carries blood between the heart and lungs, while the systemic circulation carries blood between the heart and body.
- b. The systemic circulation carries blood between the heart and lungs, while the pulmonary circulation carries blood between the heart and body.
- c. The systemic circulation carries blood between the heart and lungs, while the pulmonary circulation carries oxygen between the heart and body.
- d. The pulmonary circulation carries oxygen between the heart and lungs, while the systemic circulation carries blood between the heart and body.

e. Atherosclerosis

- a. occurs when the blood supply to part of the heart muscle is blocked.
- b. is the buildup of plaque inside arteries.
- c. consists of cell debris, cholesterol, and other substances.
- d. all of the above

f. Blood

- a. in veins carries carbon dioxide and nutrients, while blood in arteries carries oxygen and other wastes.
- b. in veins carries oxygen and nutrients, while blood in arteries carries carbon dioxide and other wastes.
- c. in arteries carries oxygen and nutrients, while blood in veins carries carbon dioxide and other wastes.
- d. in arteries carries carbon dioxide and nutrients, while blood in veins carries oxygen and other wastes.

g. Plasma includes

- a. white blood cells.
- b. red blood cells.
- c. platelets.
- d. all of the above.
- h. Roles of blood include which of the following? (1) defending the body against infection, (2) repairing body tissues, (3) transporting water from the lungs to body cells (4) controlling the body's pH.
 - a. 1 and 2
 - b. 1, 2, and 3
 - c. 1, 2, and 4
 - d. 1, 2, 3, and 4

Chapter 23. The Circulatory, Respiratory, Digestive, and Excretory Systems Worksheets

23.2 The Respiratory System

Name	Class	Date	
Write true ij	f the statement is true or false i	if the statement is false.	
1. Th	ne exchange of gases between t	the body and the outside air	is called breathing.
2. Re	espiration begins with gas exch	nange.	
3. Re	espiration and cellular respirati	on are different.	
4. Pu	ilmonary gas exchange occurs	in the alveoli of the lungs.	
5. As	sthma is a disease in which the	air passages of the lungs pe	eriodically become too large.
6. Ox	xygenated blood is transported	by the respiratory system f	rom lungs to tissues throughout the body.
7. Th	ne mouth is an organ of the resp	piratory system.	
8. Ve	entilation is the process of mov	ring air into and out of the lu	ings.
9. Pu	almonary gas exchange is the e	exchange of gases between i	nhaled air and the blood.
10. Т	The heart pumps the oxygen-ric	ch blood into your veins, wh	nich carry it throughout the body.
11. B	Body cells have a much higher	concentration of oxygen tha	nn blood in the peripheral capillaries.
12. T	The regular, rhythmic contraction	ons of the diaphragm are co	ntrolled by the brain stem.
	Carbon dioxide from body cells	s travels in the blood back to	the heart, then to the lungs where it is inhaled
again.			
	Emphysema is a lung disease us		
15. C	Gas exchange is extremely important	ortant in maintaining home	ostasis.
Lesson 2	23.2: Critical Reading		
Name	Class	Date	
Read these	passages from the text and ans	wer the questions that follow	w.

Journey of a Breath of Air

Take in a big breath of air through your nose. As you inhale, you may feel the air pass down your throat and notice your chest expand. Now exhale and observe the opposite events occurring. Inhaling and exhaling may seem like simple actions, but they are just part of the complex process of respiration, which includes these four steps:

- a. Ventilation.
- b. Pulmonary gas exchange.
- c. Gas transport.

d. Peripheral gas exchange.

Ventilation

Respiration begins with **ventilation**. This is the process of moving air in and out of the lungs. The **lungs** are the organs in which gas exchange takes place between blood and air.

- Air enters the respiratory system through the nose. As the air passes through the nasal cavity, mucus and hairs trap any particles in the air. The air is also warmed and moistened so it won't harm delicate tissues of the lungs.
- Next, the air passes through the **pharynx**, a long tube that is shared with the digestive system. A flap of connective tissue called the epiglottis closes when food is swallowed to prevent choking.
- From the pharynx, air next passes through the **larynx**, or voice box. The larynx contains vocal cords, which allow us to produce vocal sounds.
- After the larynx, air moves into the **trachea**, or wind pipe. This is a long tube that leads down to the chest.
- In the chest, the trachea divides as it enters the lungs to form the right and left bronchi. The bronchi contain cartilage, which prevents them from collapsing. Mucus in the bronchi traps any remaining particles in air. Tiny hairs called cilia line the bronchi and sweep the particles and mucus toward the throat so they can be expelled from the body.
- Finally, air passes from the bronchi into smaller passages called bronchioles. The bronchioles end in tiny air sacs called alveoli.

Questions

1.	Describe	the	iourney	of	air	during	ventilation.

2. What happens to air in the nasal cavity?

3. What is the role of the larynx?

4	What	happens	in	the	hror	ichi?

™ T		D 4
Name	Class	Date
Manic	Class	Daic

Circle the letter of the correct choice.

- a. The functions of the respiratory system include which of the following? (1) bringing air containing oxygen into the body, (2) releasing carbon dioxide into the atmosphere, (3) exchanging oxygen with carbon dioxide in blood cells, (4) transporting oxygen to cells throughout the body.
 - a. 1 only
 - b. 1 and 2
 - c. 1, 2, and 3
 - d. 1, 2, 3, and 4
- b. The four steps of respiration are
 - a. ventilation, central gas exchange, gas transport, peripheral gas exchange.
 - b. ventilation, pulmonary gas transport, gas exchange, peripheral gas transport.

- c. ventilation, pulmonary gas exchange, gas transport, peripheral gas exchange.
- d. breathing, pulmonary gas exchange, central gas exchange, peripheral gas exchange.

c. Inhaling

- a. occurs when the diaphragm contracts.
- b. occurs when the diaphragm relaxes.
- c. is the exchange of gas between blood cells and the lungs.
- d. is when oxygen in the air is drawn into the body and carbon dioxide is released from the body.

d. Respiration begins with

- a. gas transport between the mouth and the atmosphere.
- b. ventilation, the process of moving air in and out of the lungs.
- c. ventilation between the lungs and the blood.
- d. gas exchange between the lungs and the blood.

e. Ventilation involves which organs?

- a. the larynx, pharynx, and trachea
- b. the lungs, larynx, pharynx, and trachea
- c. the heart and lungs, larynx, pharynx, and trachea
- d. the heart, blood and lungs, larynx, pharynx, and trachea

f. Gas exchange occurs

- a. in the lungs, between the blood and the air.
- b. in the alveoli of the lungs, between the peripheral capillaries and lung cells.
- c. in the alveoli of the lungs, between the peripheral capillaries and body cells.
- d. all of the above

g. Emphysema

- a. results in less gas can be exchanged in the lungs.
- b. is caused by smoking and is irreversible.
- c. causes shortness of breath.
- d. all of the above

h. Asthma occurs when the

- a. some of the alveoli of the lungs fill with fluid so gas exchange cannot occur.
- b. air passages of the lungs periodically become too narrow, often with excessive mucus production.
- c. walls of the alveoli break down so less gas can be exchanged in the lungs.
- d. all of the above

Read thes	se passages from the to	ext and answer the q	questions that follow.

Digestion and Absorption: The Small Intestine

The **small intestine** is a narrow tube about 7 meters (23 feet) long in adults. It is the site of most chemical digestion and virtually all absorption. The small intestine consists of three parts: the duodenum, jejunum, and ileum.

Digestion in the Small Intestine

The duodenum is the first and shortest part of the small intestine. Most chemical digestion takes place here, and many digestive enzymes are active in the duodenum (see **Table 23.1**). Some are produced by the duodenum itself. Others are produced by the pancreas and secreted into the duodenum.

TABLE 23.1: Digestive Enzymes Active in the Duodenum"

Enzyme	What It Digests	Where It Is Made
Amylase	carbohydrates	pancreas
Trypsin	proteins	pancreas
Lipase	lipids	pancreas
Maltase	carbohydrates	duodenum
Peptidase	proteins	duodenum
Lipase	lipids	duodenum

The **liver** is an organ of both digestion and excretion. It produces a fluid called **bile**, which is secreted into the duodenum. Some bile also goes to the **gall bladder**, a sac-like organ that stores and concentrates bile and then secretes it into the small intestine. In the duodenum, bile breaks up large globules of lipids into smaller globules that are easier for enzymes to break down. Bile also reduces the acidity of food entering from the highly acidic stomach. This is important because digestive enzymes that work in the duodenum need a neutral environment. The pancreas contributes to the neutral environment by secreting bicarbonate, a basic substance that neutralizes acid.

Absorption in the Small Intestine

The jejunum is the second part of the small intestine, where most nutrients are absorbed into the blood. The mucous membrane lining the jejunum is covered with millions of microscopic, fingerlike projections called **villi** (singular, villus). Villi contain many capillaries, and nutrients pass from the villi into the bloodstream through the capillaries. Because there are so many villi, they greatly increase the surface area for absorption. In fact, they make the inner surface of the small intestine as large as a tennis court!

The ileum is the third part of the small intestine. A few remaining nutrients are absorbed here. Like the jejunum, the inner surface of the ileum is covered with villi that increase the surface area for absorption.

Questions

1. V	What	happens	in the	small	intestine	?
------	------	---------	--------	-------	-----------	---

2. List and describe three enzymes of the small intestine.

3. What is bile? What is the function of bile?

Lesson 23.3: Multiple Choice

Name_____ Class____ Date____

Circle the letter of the correct choice.

- a. The gastrointestinal tract is a long tube that includes
 - a. the mouth, stomach, intestines and anus.
 - b. the mouth, stomach, intestines, liver and anus.
 - c. the mouth, stomach, intestines, liver, gallbladder and anus.
 - d. the mouth, stomach, intestines, liver, gallbladder, pancreas and anus.
- b. The organs of the GI tract are lined with
 - a. enzymes that break down food.
 - b. cilia to sweep food through the GI tract.
 - c. mucous membranes that secrete digestive enzymes and absorb nutrients.
 - d. all of the above.

- c. Which of the following statements is the best description of digestion?
 - a. Mechanical digestion is the physical breakdown of food, and chemical digestion is the chemical breakdown of food molecules.
 - b. Chemical digestion is the physical breakdown of food, and mechanical digestion is the chemical breakdown of food molecules.
 - c. Chemical digestion is the physical breakdown of food, and mechanical digestion is the mechanical breakdown of food molecules.
 - d. Mechanical digestion occurs in your mouth, and chemical digestion occurs in your stomach.

d. In your mouth,

- a. pepsin begins the acidic digestion of proteins.
- b. amylase begins the chemical digestion of carbohydrates.
- c. amylase begins the mechanical digestion of carbohydrates.
- d. amylase, pepsin, trypsin, and other enzymes start to break down food.

e. The stomach

- a. digests food both mechanically and chemically.
- b. contains pepsin, which chemically digests protein.
- c. has an acidic environment, which kills bacteria in food and is needed for the stomach enzymes to function.
- d. all of the above

f. In the small intestine,

- a. most nutrients from food are absorbed into the blood.
- b. excess water is absorbed from food.
- c. the mechanical breakdown of food is completed.
- d. partly digested food is stored until ready for the final aspects of digestion.

g. The large intestine includes

- a. the duodenum, jejunum, and ileum.
- b. the GI tract, from the mouth to the anus.
- c. the cecum, colon, and rectum.
- d. the duodenum, jejunum, ileum, cecum, colon, and rectum.

h. Nutrients

- a. include carbohydrates, proteins, lipids, and water.
- b. are needed for energy, building materials, and control of body processes.
- c. include chemical elements like calcium and potassium.
- d. all of the above

Excretion

Excretion is the process of removing wastes and excess water from the body. It is one of the major ways the body maintains homeostasis. Although the kidneys are the main organs of excretion, several other organs also excrete wastes. They include the large intestine, liver, skin, and lungs. All of these organs of excretion, along with the kidneys, make up the **excretory system**. This lesson focuses on the role of the kidneys in excretion. The roles of the other excretory organs are summarized below:

Read these passages from the text and answer the questions that follow.

- The large intestine eliminates solid wastes that remain after the digestion of food.
- The liver breaks down excess amino acids and toxins in the blood.
- The skin eliminates excess water and salts in sweat.
- The lungs exhale water vapor and carbon dioxide.

Lesson Summary

- The kidneys filter blood and form urine. They are part of the urinary system, which also includes the ureters, bladder, and urethra.
- Each kidney has more than a million nephrons, which are the structural and functional units of the kidney. Each nephron is like a tiny filtering plant.
- The kidneys maintain homeostasis by controlling the amount of water, ions, and other substances in the blood.
- be

 They also secrete hormones that have other homeostatic functions. Kidney diseases include kidney stones, infections, and kidney failure due to diabetes. treated with dialysis. 	Kidney failure may

24.1 Nonspecific Defenses

Name	Class	Date
Write true if the state	ment is true or false if t	the statement is false.
1. The skin is	the single most importa	ant defense the body has.
2. Sneezing re	moves pathogens from	your nose.
3. Sweat, muc	us, tears, and saliva are	all types of mechanical barriers used to protect you.
4. The inflamr	natory response is part of	of the body's first line of defense.
5. Leukocytes	are white blood cells th	nat fight infections and get rid of debris.
6. Barriers tha	t keep out pathogens are	e the body's first line of defense.
7. The second	line of defense attacks 1	pathogens that manage to enter the body.
8. The second	line of defense includes	s mechanical, chemical, and biological barriers.
9. The first lin	e of defense includes th	e inflammatory response and phagocytosis.
10. A nonspec	ific defense can be tailo	ored to a particular pathogen.
11. The inflam	matory response is trigg	gered by chemicals called histakines and cytomines.
12. Biological	barriers include million	ns of harmless bacteria live on the human skin.
Lesson 24.1: C	ritical Reading	
Name	Class	Date

The body's first line of defense consists of different types of barriers that keep most pathogens out of the body. **Pathogens** are disease-causing agents, such as bacteria and viruses. These and other types of pathogens are described

in the figure below. Regardless of the type of pathogen, however, the first line of defense is always the same.

The First Line of Defense

Type of pathogen	Description	Human diseases caused by pathogens of that type	
Bacteria Escherichia coll	Single-celled organisms without a nucleus	Strep throat, staph infections, tuberculosis, food poisoning, tetanus, pneumona, syphilis	
Viruses Herpes simplex	Non living particles that reproduce by taking over living cells	Common cold, flu, genital herpes, col sores, measle, AIDS, genital warts, chicken pox, small pox	
Fungi Death cap mushroom	Simple organisms, including mushrooms and yeasts, that grow as single cells or thread like filaments.	Ringworm, athlete's foot, tineas, candidiasis, histoplasmosis, mushroom poisoning	
Protozoa Giardia lamblia	Single-celled organism with a nucleus.	Malaria, "traveller's diarrhea" giardiasis, typano somiasis ("sleeping sickness")	

Types of pathogens that commonly cause human diseases include bacteria, viruses, fungi, and protozoa. Which type of pathogen causes the common cold? Which type causes athlete's foot? (From top to bottom, images courtesy of Rocky Mountain Laboratories/NIAID/NIH and under the public domain, courtesy of CDC/Dr. Erskine Palmer and under the public domain, courtesy of Archenzo and under GNU-FDL 1.2, and courtesy of CDC/Janice Carr and under the public domain. Composite created by CK-12 Foundation.)

Mechanical Barriers

Mechanical barriers physically block pathogens from entering the body. The skin is the most important mechanical barrier. In fact, it is the single most important defense the body has. The outer layer of the skin is tough and very difficult for pathogens to penetrate. **Mucous membranes** provide a mechanical barrier at body openings. They also line the respiratory, GI, urinary, and reproductive tracts. Mucous membranes secrete **mucus**, a slimy substance that traps pathogens. The membranes also have hair-like cilia. The cilia sweep mucus and pathogens toward body openings where they can be removed from the body. When you sneeze or cough, pathogens are removed from the nose and throat. Tears wash pathogens from the eyes, and urine flushes pathogens out of the urinary tract.

Chemical Barriers

Chemical barriers destroy pathogens on the outer body surface, at body openings, and on inner body linings. Sweat, mucus, tears, and saliva all contain enzymes that kill pathogens. Urine is too acidic for many pathogens, and semen contains zinc, which most pathogens cannot tolerate. In addition, stomach acid kills pathogens that enter the GI tract in food or water.

Biological Barriers

Biological barriers are living organisms that help protect the body. Millions of harmless bacteria live on the human skin. Many more live in the GI tract. The harmless bacteria use up food and space so harmful bacteria cannot grow.

Questions

1. What is a pathogen? Which type of pathogen causes the common cold? Which type causes athlete's foot?

2. What is meant by *The First Line of Defense?*

3. What is a mechanical barrier? Give an example.

4. What is a chemical barrier? Give an example.

5. What is a biological barrier? Give an example.

Lesson	24.1:	Multip	ole (Choice
--------	-------	--------	-------	--------

Name	Class	Date

Circle the letter of the correct choice.

- a. Which statement best describes the immune system?
 - a. The immune system produces gametes.
 - b. The immune system exchanges gases between the blood and lungs.
 - c. The immune system protects the body from pathogens.
 - d. The immune system digests food into usable nutrients.
- b. The immune system is comprised of _____ lines of defense.
 - a. two
 - b. three
 - c. four
 - d. five
- c. Which statement best describes the first line of defense?
 - a. The first line of defense consists of different types of barriers that keep most pathogens out of the body.
 - b. The first line of defense includes the inflammatory response.
 - c. Leukocytes are the cells responsible for the first line of defense.
 - d. The first line of defense includes the skin, mucous membranes and biological barriers such as white blood cells.
- d. Which statements are true about mechanical barriers? (1) Mechanical barriers physically block pathogens from entering the body. (2) The skin is the most important mechanical barrier. (3) Mechanical barriers are living organisms that help protect the body. (4) Mechanical barriers destroy pathogens on the outer body surface.
 - a. 1 and 2
 - b. 3 and 4
 - c. 1, 2, and 3
 - d. 1, 2, 3, and 4
- e. Which statement describes the second line of defense?
 - a. The second line of defense includes biological and chemical barriers.
 - b. The skin is the major organ of the second line of defense.
 - c. The second line of defense keeps most pathogens out of the body.
 - d. The second line of defense is encountered by pathogens that enter the body.
- f. What is the inflammatory response?
 - a. The inflammatory response begins when cytokines or histamines infect a tissue.
 - b. The inflammatory response is the first reaction of the body to tissue damage or infection.
 - c. The inflammatory response is a chemical barrier that destroys pathogens on the body surface.
 - d. none of the above
- g. Leukocytes
 - a. are red blood cells that bring extra oxygen to the site of infection.
 - b. are biological barriers that help protect the body.
 - c. are white blood cells that fight infections and get rid of debris.
 - d. are released by mucous membranes at body openings.
- h. Phagocytosis

- a. is the process in which leukocytes engulf and break down pathogens and debris.
- b. are chemical barriers destroy pathogens.
- c. are part of the first line of defense.
- d. all of the above

Name	Class	Date
Fill in the blank	k with the appropriate term.	
1	are disease-causing agents,	such as bacteria and viruses.
2	is the process in which cells	s engulf and break down pathogens and debris.
3. The skin	is the single most i	important defense the body has.
4. The	response is the first rea	action of the body to tissue damage or infection.
5	membranes secrete mucus,	a slimy substance that traps pathogens.
6	barriers destroy pathogens of	on the outer body surface.
7. Leukocytes a	are blood cells	that fight infections and get rid of debris.
8. A	defense is tailored to a pa	articular pathogen.
9. A	defense is the same no m	natter what type of pathogen is involved.
10. Millions of	harmless live o	on the human skin.
11. Mucous me	embranes provide a	barrier at body openings.
12. Sweat, muc	eus, tears, and saliva all contain	n that kill pathogens.
13. The	line of defense attacks	s pathogens that manage to enter the body.
14. Barriers tha	at keep out pathogens are the be	ody's line of defense.
Lesson 24.	1: Critical Writing	
Name	Class	Date

Thoroughly answer the question below. Use appropriate academic vocabulary and clear and complete sentences.

Describe the barriers that keep most pathogens out of the human body.

24.2 The Immune Response

1. The 2. The 3. Lym 4. Lym	the statement is true or false if the statement is false. third line of defense is referred to as the immune response. lymphatic system produces leukocytes called lymphocytes. phocytes can destroy certain cancer cells. ph is a fluid that leaks out of cells into spaces between capillaries.
2. The 3. Lym 4. Lym	lymphatic system produces leukocytes called lymphocytes. phocytes can destroy certain cancer cells.
3. Lym 4. Lym	phocytes can destroy certain cancer cells.
4. Lym	
•	ph is a fluid that leaks out of cells into spaces between capillaries.
5. The	pri le u riulu unu reune eur er erie spure erie upriuries.
	human body has as many as two billion lymphocytes.
6. Anti	gens trigger the immune system to react against the cells that carry them.
7. T ce	lls mature in bone marrow, and B cells mature in the thymus.
8. B ce	lls must be activated by an antigen before they can fight pathogens.
9. Anti	bodies are large, Y-shaped proteins that recognize and bind to antigens.
10. The	e cell-mediated immune response leads to the destruction of cells that are infected with viruses.
11. He	lper T cells destroy virus-infected cells and some cancer cells.
12. Cy	totoxic T cells suppress other T cells that mistakenly react against self antigens.
13. Me	mory B and T cells help protect the body from re-infection by pathogens.
14. Sin	ce antibodies are such important proteins, they can recognize many types of antigens.
15. Imi	munization is a form of passive immunity.

Lymphatic System

The immune response mainly involves the lymphatic system. The **lymphatic system** is a major part of the immune system. It produces leukocytes called lymphocytes. **Lymphocytes** are the key cells involved in the immune response. They recognize and help destroy particular pathogens in body fluids and cells. They also destroy certain cancer cells.

Structures of the Lymphatic System

The structures of the lymphatic system include organs, lymph vessels, lymph, and lymph nodes. Organs of the lymphatic system are the bone marrow, thymus, spleen, and tonsils.

• Bone marrow is found inside many bones. It produces lymphocytes.

- The thymus is located in the upper chest behind the breast bone. It stores and matures lymphocytes.
- The spleen is in the upper abdomen. It filters pathogens and worn out red blood cells from the blood, and then lymphocytes in the spleen destroy them.
- The tonsils are located on either side of the pharynx in the throat. They trap pathogens, which are destroyed by lymphocytes in the tonsils.

Lymphocytes

The human body has as many as two trillion lymphocytes, and lymphocytes make up about 25% of all leukocytes. The majority of lymphocytes are found in the lymphatic system, where they are most likely to encounter pathogens. The rest are found in the blood. There are two major types of lymphocytes, called **B cells** and **T cells**. These cells get their names from the organs in which they mature. B cells mature in bone marrow, and T cells mature in the thymus. Both B and T cells recognize and respond to particular pathogens.

Antigen Recognition

B and T cells actually recognize and respond to antigens on pathogens. Antigens are molecules that the immune system recognizes as foreign to the body. Antigens are also found on cancer cells and the cells of transplanted organs. They trigger the immune system to react against the cells that carry them. This is why a transplanted organ may be rejected by the recipient's immune system. How do B and T cells recognize specific antigens? They have receptor molecules on their surface that bind only with particular antigens.

Questions

1.	What are	lymphocytes?	What is	their	function?

2. List the organs of the lymphatic system. Describe the functions of two of these organs.

3. Define B cells and T cells.

1	Whata		tiaana	c
4.	What a	ıre an	ugens	į

5. How do B and T cells recognize specific antigens?

Lesson 24.2: Multiple Choice

Name_____ Class____ Date____

Circle the letter of the correct choice.

- a. The immune response
 - a. is specific to a particular pathogen.
 - b. is the third line of defense.
 - c. allows the immune system to "remember" the pathogen after the infection is over.
 - d. all of the above
- b. The immune response mainly involves the
 - a. lymphatic system.
 - b. spleen and tonsils.
 - c. blood cells.
 - d. antibodies and lymphocytes.

c. Organs of the lymphatic system include

- a. the spleen, which filters and destroys lymphocytes.
- b. the thymus, which stores and matures antibodies.
- c. bone marrow, which produces lymphocytes.
- d. all of the above.

d. Which statement concerning lymphocytes is correct?

- a. B cells mature in bone marrow, and T cells mature in the thymus, and both B and T cells recognize and respond to particular pathogens.
- b. B cells mature in bone marrow, and T cells mature in the thymus, and both B and T cells recognize and respond to particular lymphocytes.
- c. B cells mature in bone, and T cells mature in the thymus, and both B and T cells recognize and respond to particular pathogens.
- d. B cells mature in bone, and T cells mature in the thymus, and both B and T cells recognize and respond to particular lymphocytes.

e. The humoral immune response

- a. involves mainly T cells and takes place in blood and lymph.
- b. involves mainly B cells and takes place in blood and lymph.
- c. involves mainly antibodies and takes place in blood and lymph.
- d. involves mainly antigens and takes place in blood and lymph.

f. Antibodies are

- a. large, Y-shaped proteins that recognize and bind to antigens.
- b. large, X-shaped proteins that recognize and bind to antigens.
- c. large, Y-shaped proteins that recognize and bind to lymphocytes.
- d. large, X-shaped proteins that recognize and bind to lymphocytes.

g. The cell-mediated immune response

- a. involves mainly B cells and leads to the destruction of cells that are infected with lymphocytes.
- b. involves mainly T cells and leads to the destruction of cells that are infected with lymphocytes.
- c. involves mainly B cells and leads to the destruction of cells that are infected with viruses.
- d. involves mainly T cells and leads to the destruction of cells that are infected with viruses.

h. Active immunity

- a. can last a lifetime.
- b. can result from an immunization.
- c. results when an immune response to a pathogen produces memory cells.
- d. all of the above

Lesson 24.2: Vocabulary I			
Name	Class	Date

24.3 Immune System Diseases

Less	on 24.3: True or False
Name	Class Date
Write	rue if the statement is true or false if the statement is false.
	1. AIDS is not a single disease but a set of diseases.
	2. AIDS occurs with elevated levels of helper T cells.
	3. The HIV frequently mutates and changes its surface antigens.
	4. Autoimmune diseases occur when the immune system attacks itself.
antige:	5. An allergen is a disease in which the immune system makes an inflammatory response to a harmles
	6. Any allergen that causes an allergy is an antigen.
	7. Ragweed pollen and poison ivy are two common causes of allergies.
	8. Allergies can be very dangerous, even life-threatening.
	9. Histamines can reduce or eliminate the effects of the antihistamines that cause allergy symptoms.
	10. Multiple sclerosis attacks the insulin-producing cells of the pancreas.
	11. Systemic lupus erythematosus can attack the joints, heart, and other organs.
	12. Immunodeficiency can occur naturally in older individuals.
	13. Immunodeficiency can occur in people who have undergone organ transplants.
	14. AIDS is a virus that attacks the immune system.
	15. Because HIV screening is not accurate, donated blood can still be infected with the virus.
Less	on 24.3: Critical Reading
Name	Class Date

Autoimmune Diseases

Autoimmune diseases occur when the immune system fails to recognize the body's own molecules as "self," or belonging to the person. Instead, it attacks body cells as though they were dangerous pathogens. Some relatively common autoimmune diseases are listed in **Table 24.1**. These diseases cannot be cured, although they can be treated to relieve symptoms and prevent some of the long-term damage they cause.

Read these passages from the text and answer the questions that follow.

TABLE 24.1: Autoimmune Diseases

Name of Disease	Tissues Attacked by Immune Sys-	Results of Immune System Attack
	tem	
Rheumatoid arthritis	tissues inside joints	joint damage and pain
Type 1 diabetes	insulin-producing cells of the pan-	inability to produce insulin, high
	creas	blood sugar
Multiple sclerosis	myelin sheaths of central nervous	muscle weakness, pain, fatigue
-	system neurons	-
Systemic lupus erythematosus	joints, heart, other organs	joint and organ damage and pain

Why does the immune system attack body cells? In some cases, it's because of exposure to pathogens that have antigens similar to the body's own molecules. When this happens, the immune system not only attacks the pathogens. It also attacks body cells with the similar molecules.

Immunodeficiency

Immunodeficiency occurs when the immune system is not working properly. As a result, it cannot fight off pathogens that a normal immune system would be able to resist. Rarely, the problem is caused by a defective gene. More often, it is acquired during a person's lifetime. Immunodeficiency may occur for a variety of reasons:

- The immune system naturally becomes less effective as people get older. This is why older people are generally more susceptible to disease.
- The immune system may be damaged by other disorders, such as obesity or drug abuse.
- Certain medications can suppress the immune system. This is an intended effect of drugs given to people with transplanted organs. In many cases, however, it is an unwanted side effect of drugs used to treat other diseases.
- Some pathogens attack and destroy cells of the immune system. An example is the virus known as HIV. It is the most common cause of immunodeficiency in the world today.

4. What is immunodeficiency?

5. Immunodeficiency may occur for a variety of reasons. Describe two of these reasons.

Lesson 24.3: Multiple Choice

Name_____ Class____ Date____

Circle the letter of the correct choice.

- a. What is an allergy?
 - a. An allergy is a disease in which the immune system makes an inflammatory response to a harmless antibody.
 - b. An allergy is a disease in which the immune system makes an inflammatory response to a harmless antigen.
 - c. An allergy is a disease in which the lymphatic system makes an inflammatory response to a harmless antigen.
 - d. An allergy is a disease in which the immune system destroys harmless pathogens.
- b. Two common causes of allergies are

- a. ragweed and poison ivy.
- b. ragweed and poison roses.
- c. poison ragweed and ivy.
- d. all of the above.

c. An autoimmune disease

- a. occurs when the immune system initiates an immune response against foreign pathogens.
- b. occurs when the immune system attacks the body's own pathogens.
- c. occurs when the immune system fails to recognize the body's own molecules as belonging to the person.
- d. occurs when the immune system fails to recognize foreign molecules as belonging to the person.

d. Type 1 diabetes

- a. attacks the insulin-producing cells of the pancreas.
- b. is an autoimmune disease.
- c. results in high blood sugar levels.
- d. all of the above

e. Causes of immunodeficiency include

- a. damage of the immune system by other disorders.
- b. suppression of the immune system by certain medications.
- c. destruction of cells of the immune system by pathogens.
- d. all of the above.
- f. Which statement is true of the relationship between HIV and AIDS?
 - a. HIV causes AIDS.
 - b. AIDS causes HIV.
 - c. HIV and AIDS are the same disease.
 - d. HIV and AIDS are not related.

g. HIV transmission

- a. can occur through saliva.
- b. occurs through the direct contact of mucous membranes or some body fluids.
- c. can occur through kissing.
- d. all of the above

h. AIDS occurs

- a. when helper T cells fall to a very low level.
- b. about 3-5 years after an HIV infection.
- c. when HIV levels match the level of helper T cells.
- d. after years of damage to the immune system by helper T cells.

Read ti	ese passages from the text and answer	the questions that follow.

Carcinogens and Cancer

A **carcinogen** is anything that can cause cancer. Cancer is a disease in which cells divide out of control. Most carcinogens cause cancer by producing mutations in DNA.

Types of Carcinogens

There are several different types of carcinogens. They include pathogens, radiation, and chemicals. Some carcinogens occur naturally. Others are produced by human actions.

- Viruses cause about 15 percent of all human cancers. For example, the virus called hepatitis B causes liver cancer.
- UV radiation is the leading cause of skin cancer. The radioactive gas known as radon causes lung cancer.
- Tobacco smoke contains dozens of carcinogens, including nicotine and formaldehyde. Exposure to tobacco smoke is the leading cause of lung cancer.

• Some chemicals that were previously added to foods, such as certain dyes, are now known to cause cancer. Cooking foods at very high temperatures also causes carcinogens to form.

How Cancer Occurs

Mutations that lead to cancer usually occur in genes that control the cell cycle. These include tumor-suppressor genes and proto-oncogenes.

- Tumor-suppressor genes normally prevent cells with damaged DNA from dividing. Mutations in these genes prevent them from functioning normally. As a result, cells with damaged DNA are allowed to divide.
- Proto-oncogenes normally help control cell division. Mutations in these genes turn them into oncogenes. Oncogenes promote the division of cells with damaged DNA.

Cells that divide uncontrollably may form a tumor, or abnormal mass of cells. Tumors may be benign or malignant. Benign tumors remain localized and generally do not harm health. Malignant tumors are cancerous. There are no limits to their growth, so they can invade and damage neighboring tissues. Cells from malignant tumors may also break away from the tumor and enter the bloodstream. They are carried to other parts of the body, where new tumors may form.

may form.	
Questions	
1. What is a carcinogen? What is cancer?	
2. Describe two carcinogens.	
2. Describe two caremogens.	

3. What is a tumor-suppressor gene?

4. What is a proto-oncogene?

5. Discuss how a malignant tumor can cause cancer.

Lesson 24.4: Multiple Choice

Name	Class	Date	
lanic	Class	Date	

Circle the letter of the correct choice.

- a. Which statement is true concerning cancer?
 - a. Most carcinogens cause cancer by producing mutations in DNA.
 - b. Cancer is a disease in which cells divide out of control.
 - c. A carcinogen is anything that can cause cancer.
 - d. all of the above
- b. Carcinogens include
 - a. viruses, which cause about 50 percent of all human cancers.
 - b. UV radiation, which is the leading cause of lung cancer.
 - c. exposure to tobacco smoke, which is the leading cause of skin cancer.
 - d. none of the above.
- c. The most common deadly cancer in the United States is
 - a. skin cancer.
 - b. lung cancer.
 - c. breast cancer.
 - d. prostate cancer.
- d. Tumor-suppressor genes
 - a. help cells with damaged DNA to divide.
 - b. normally help control cell division.
 - c. prevent cells with damaged DNA from dividing.

- d. normally help stop cell division.
- e. Warning signs of cancer include
 - a. a lump in the breast or elsewhere.
 - b. an obvious changes in a wart or mole.
 - c. an unusual bleeding or discharge.
 - d. all of the above.
- f. The Air Quality Index
 - a. measures levels of ground-level ozone and particulates.
 - b. is one of the main components of smog.
 - c. is harmful to people with certain health problems, such as asthma.
 - d. affects almost 5 million people each year.
- g. Bioterrorism
 - a. contains dozens of carcinogens, and is the leading cause of lung cancer.
 - b. is the intentional release of disease causing viruses, bacteria, or other toxins.
 - c. includes pollutants in the outdoor air.
 - d. includes anything that causes cancer.
- h. Air pollution

Terms

- a. can make asthma and other diseases more severe.
- b. can cause skin cancer.
- c. is the leading cause of lung cancer.
- d. all of the above

Read these pass	sages from the text and answer the questions that follow.

Sexual Development in Males

The only obvious difference between boys and girls at birth is their reproductive organs. However, even the reproductive organs start out the same in both sexes.

Development Before Birth

In the first several weeks after fertilization, males and females are essentially the same except for their chromosomes. Females have two X chromosomes (XX), and males have an X and a Y chromosome (XY). Then, during the second month after fertilization, genes on the Y chromosome of males cause the secretion of testosterone. Testosterone stimulates the reproductive organs to develop into male organs. (Without testosterone, the reproductive organs

always develop into female organs.) Although boys have male reproductive organs at birth, the organs are immature and not yet able to produce sperm or secrete testosterone.

Puberty and Its Changes

The reproductive organs grow very slowly during childhood and do not mature until puberty. **Puberty** is the period during which humans become sexually mature. In the U.S., boys generally begin puberty at about age 12 and complete it at about age 18. What causes puberty to begin? The hypothalamus in the brain "tells" the pituitary gland to secrete hormones that target the testes. The main pituitary hormone involved is **luteinizing hormone** (**LH**). It stimulates the testes to secrete testosterone. Testosterone, in turn, promotes protein synthesis and growth. It brings about most of the physical changes of puberty.

about most of the physical changes of puberty.
Questions
1. What is the difference between the male and female chromosomes?
2. Describe the role of testosterone during development.
3. Define "puberty." When does puberty begin in boys?

4. What causes puberty to begin?

5. What is luteinizing hormone? What does it do?

Lesson 25.1: Multiple Choice

Name	Class	Date

- a. Which statement best describes a gamete?
 - a. A gamete is a sex cell.
 - b. A gamete is a cell involved in reproduction.
 - c. A gamete is a haploid reproductive cell that combines with another haploid gamete during fertilization.
 - d. Gametes combine during fertilization.
- b. Structures of the male reproductive system include which of the following? (1) the vas deferens, (2) the epididymis, (3) the fallopian tubes, (4) the seminiferous tubules.
 - a. 1 and 2
 - b. 1, 2, and 3
 - c. 1, 2, and 4
 - d. 1, 2, 3, and 4
- c. In boys, the adolescent growth spurt
 - a. is controlled by testosterone.
 - b. can be about 10 centimeters per year.
 - c. rapidly continues for several years.
 - d. all of the above
- d. During spermatogenesis,
 - a. sperm are produced in the seminiferous tubules of the testes and become mature in the epididymis.
 - b. sperm are produced in the epididymis of the testes and become mature in the seminiferous tubules.
 - c. sperm are produced in the vas deferens of the testes and become mature in the epididymis.

- d. sperm are produced in the vas deferens of the testes and become mature in the seminiferous tubules.
- e. Structures of a mature sperm cell include
 - a. a tail.
 - b. the mitochondrial segment.
 - c. an acrosome.
 - d. all of the above.
- f. What causes puberty to begin?
 - a. The secretion of testosterone from the testes.
 - b. The initial release of luteinizing hormone from the pituitary gland.
 - c. New protein synthesis and growth.
 - d. The development of testes.
- g. The epididymis
 - a. is a very long coiled tube inside the scrotum.
 - b. is where sperm mature.
 - c. is where sperm are stored.
 - d. all of the above
- h. How many sperm are released with each ejaculation?
 - a. hundreds
 - b. thousands
 - c. millions
 - d. hundreds of millions

Read	these passages from the text and answer the questions that follow.

Egg Production

At birth, a female's ovaries contain all the eggs she will ever produce. However, the eggs do not start to mature until she enters puberty. After menarche, one egg typically matures each month until a woman reaches middle adulthood.

Oogenesis

The process of producing eggs in the ovary is called **oogenesis**. Eggs, like sperm, are haploid cells, and their production occurs in several steps that involve different types of cells, as shown in the figure below. You can follow the process of oogenesis in the figure as you read about it below.

(Image courtesy of Mysid and under the public domain.)

Oogenesis begins long before birth when an oogonium with the diploid number of chromosomes undergoes mitosis. It produces a diploid daughter cell called a primary oocyte. The primary oocyte, in turn, starts to go through the first cell division of meiosis (meiosis I). However, it does not complete meiosis until much later. The primary oocyte remains in a resting state, nestled in a tiny, immature follicle until puberty.

Maturation of a Follicle

Beginning in puberty, each month one of the follicles and its primary oocyte starts to mature. The primary oocyte resumes meiosis and divides to form a secondary oocyte and a smaller cell, called a polar body. Both the secondary oocyte and polar body are haploid cells. The secondary oocyte has most of the cytoplasm from the original cell and is much larger than the polar body.

Ovulation and Fertilization

After 12–14 days, when the follicle is mature, it bursts open, releasing the secondary oocyte from the ovary. This event is called **ovulation**. The follicle, now called a corpus luteum, starts to degenerate, or break down. After the secondary oocyte leaves the ovary, it is swept into the nearby Fallopian tube by the waving, fringe-like end.

If the secondary oocyte is fertilized by a sperm as it is passing through the Fallopian tube, it completes meiosis and forms a mature egg and another polar body. (The polar bodies break down and disappear.) If the secondary oocyte is not fertilized, it passes into the uterus as an immature egg and soon disintegrates.

Questions

1. A man produces sperm daily after puberty. When does a women produce her eggs?

2.	What	is	oogenesis	•
----	------	----	-----------	---

3. When does the haploid egg form?

4. What is ovulation? When does ovulation occur?

5. When is meiosis competed?

Cleavage and Implantation

When a sperm penetrates the egg, it triggers the egg to complete meiosis. The sperm also undergoes changes. Its tail falls off, and its nucleus fuses with the nucleus of the egg. The resulting cell, called a zygote, contains all the chromosomes needed for a new human organism. Half the chromosomes come from the egg and half from the sperm.

Morula and Blastocyst Stages

The zygote spends the next few days traveling down the Fallopian tube toward the uterus, where it will take up residence. As it travels, it divides by mitosis several times to form a ball of cells called a morula. The cell divisions

are called cleavage. They increase the number of cells but not the overall size of the new organism. As more cell divisions occur, a fluid-filled cavity forms inside the ball of cells. At this stage, the ball of cells is called a **blastocyst**. The cells of the blastocyst form an inner cell mass and an outer cell layer, as shown in the figure below. The inner cell mass is called the embryoblast. These cells will soon develop into an embryo. The outer cell layer is called the trophoblast. These cells will develop into other structures needed to support and nourish the embryo.

Blastocyst. The blastocyst consists of an outer layer of cells called the trophoblast and an inner cell mass called the embryoblast. (*This image is under GNU-FDL 1.2.*)

Implantation

The blastocyst continues down the Fallopian tube and reaches the uterus about 4 or 5 days after fertilization. When the outer cells of the blastocyst contact cells of the endometrium lining the uterus, the blastocyst embeds in the endometrium. The process of embedding is called **implantation**. It generally occurs about a week after fertilization.

Read these passa	ges from the text and answer	the questions that follow.	

Understanding Sexually Transmitted Infections

To be considered a sexually transmitted infection (STI), an infection must have only a small chance of spreading naturally in ways other than sexual contact. Some infections that can spread through sexual contact, such as the common cold, spread more commonly by other means. These infections are not considered STIs.

Pathogens that Cause STIs

STIs may be caused by several different types of pathogens, including protozoa, insects, bacteria, and viruses. For example: Protozoa cause an STI called **trichomoniasis**. The pathogen infects the vagina in females and the urethra in males, causing symptoms such as burning and itching. Trichomoniasis is common in young people. Pubic lice are insect parasites that are transmitted sexually. They suck the blood of their host and irritate the skin in the pubic area

Most STIs are caused by bacteria or viruses. Several of them are described below. Bacterial STIs can be cured with antibiotics. Viral STIs cannot be cured. Once you are infected with a viral STI, you are likely to be infected for life.

How STIs Spread

Most of the pathogens that cause STIs enter the body through mucous membranes of the reproductive organs. All sexual behaviors that involve contact between mucous membranes put a person at risk for infection. This includes vaginal, anal, and oral sexual behaviors. Many STIs can also be transmitted through body fluids such as blood, semen, and breast milk. Therefore, behaviors such as sharing injection or tattoo needles are another way these STIs can spread. Why are STIs common in young people? One reason is that young people often take risks. They may think, "It can't happen to me." They also may not know how STIs are spread, so they don't know how to protect themselves. In addition, young people may have multiple sexual partners.

Preventing STIs

The only completely effective way to prevent infection with STIs is to avoid sexual contact and other risky behaviors. Using condoms can lower the risk of becoming infected with STIs during some types of sexual activity. However, condoms are not foolproof. Pathogens may be present on areas of the body not covered by condoms. Condoms can also break or be used incorrectly.

Questions

1.	What is a sexually	transmitted infection	on? What causes	most STIs?
----	--------------------	-----------------------	-----------------	------------

2. Describe trichomoniasis.

3. How are pathogens that cause STIs transmitted?

4. What are two ways to prevent STIs? What is the main difference between the two methods discussed in the text?
